INTRODUCTION 12

TECHNICAL NOTES

Definitions, Rates and Ratios 14
Qualifications and Limitations of Data and Calculations 17

SECTION I NATALITY

Natality: An Overview. 21
Live Births 24
Fertility 29
Racial Composition. 33
Age of Mother 37
Age-Specific Live Birth Rates 37
Birth Order 43
Interpregnancy Time Period. 49
Prenatal Care 52
Birth Weight. 59
Sex of Infant 65
Mother's Education. 67
Congenital Anomalies. 70
Complications 74
Place of Occurrence 80
Place of Birth. 82
Attendant at Birth. 82
Fetal Deaths. 85
Causes of Fetal Death 87
Age of Mother and Race of Fetus 91
Interpregnancy Time Period for Fetal Deaths 93
Prenatal Care - Fetal Deaths. 96
Fetal Weight. 99

SECTION II MORTALITY

Mortality: An Overview 106
Leading Causes of Death 121
Diseases of the Heart 138
Cancer. 151
Cerebrovascular Disease 164
Accidents 176
Chronic Obstructive Pulmonary Diseases and Allied Conditions. 189
Pneumonia and Influenza 198
Diabetes Mellitus 209
Chronic Liver Disease and Cirrhosis 220
Atherosclerosis 231
Suicide 241
The Probability of Eventual Death Due to a Specified Cause. 251
Infant Deaths 253
Communicable Disease Deaths 277
Injury at Work. 277
Life Expectancy 282
Place of Occurrence 285

SECTION III MARRIAGE AND DIVORCE

PAGE

Marriage and Divorce: An Overview 291
Marriages. 292
Residence of Couples Marrying in Michigan. 292
Month of Marriage. 295
Age at Marriage. 295
Remarriages. 300
First Marriages. 307
Age at First Marriage. 312
Divorces and Annulments. 312

Table of Contents - TABULAR

INTRODUCTION

The 1979 edition of Michigan Health Statistics is a statistical summary of vital events for calendar year 1979. Data relative to population, births, deaths, fetal deaths, marriages, divorces and communicable diseases are included. Although most of the data in this report pertain to events occurring in 1979, some data for prior years have been included to illustrate trends. Most of the tabulations refer to Michigan residents. Some events, however, such as marriages and divorces are tabulated with respect to where the event occurred rather than the residence of the party or parties involved.

As a certain number of Michigan residents either deliver babies or die out of state each year, it is necessary to include data obtained from the certificates of other states in any residence tabulations pertaining to Michigan residents. This report includes all such out-of-state certificates received prior to April 24, 1980, and all in-state certificates and records received prior to March 15, 1980. Although a few records for the calendar year 1979 were received after these filing dates, their exclusion from this report is statistically insignificant.

The 1970 edition of Michigan Health Statistics contained a complete section devoted to population characteristics. Similar data are not available for 1979 and thus the 1979 edition of Michigan Health Statistics does not have a section on population. The reader is referred to the 1970 edition for detailed population characteristics and to the reference appendix of this edition for 1979 county and state population estimates. More detailed population data are available in the Bureau of Management and Budget publication "Population Projections" and in the U.S. Census Bureau P-26 series.

The report is composed of the following sections and appendices:

1. Natality Section, 2. Mortality Section, 3. Marriage and Divorce Section, 4. Reference Appendix.

Comments or suggestions concerning the content and format of this report are always welcome. Any additional needs for data or analyses may be directed to the Office of Vital and Health Statistics. A summary of prepared vital statistics tabulations, Index to Michigan Vital Statistics 1960 to Present, is also available. This index lists the type of tabulations and data available. The Office will make every attempt to comply with requests for data within the limitation of staff and resources.

TECHNICAL NOTES
DEFINITIONS, RATES AND RATIOS

DEFINITIONS

BIRTH WEIGHT-Weight of fetus or infant at time of delivery (normally recorded in pounds and ounces).

FETAL DEATH-Death prior to the complete expulsion or extraction from its mother of a product of conception, having passed through at least the 20th week of gestation or weighing at least 400 grams; the fetus shows no signs of life such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles. (Note: This includes both spontaneous and induced terminations.)

FIRST BIRTH-A live birth where the maternal medical history indicates there were no prior live births to the mother.

GESTATIONAL PERIOD-Number of weeks elapsed between the first day of the last menstral period and date of delivery.

HEBDOMADAL DEATH-Death occurring to an individual less than 7 days of age.

INFANT DEATH-Death occurring to an individual of less than 1 year of age.

INTERPREGNANCY TIME PERIOD-Birth date minus date of last termination, whether a live birth or fetal death, in months. Time periods of zero length are dropped to exclude 2nd or higher births of multiple deliveries.

LEADING CAUSES OF DEATH-Deaths are grouped into 72 categories dependent upon the underlying cause of death. Ranks are assigned by organizing these categories according to the number of deaths in each category from most frequent to least.

LIFE EXPECTANCY-A hypothetical calculation of the average age at death for a cohort of persons subject to the age-specific mortality rates observed over a given time period.

LIFE TABLE VALUES:

$_{n}q_{x}$ = The proportion of persons in the cohort alive at the beginning of an age interval (x) who will die before reaching the end of that age interval (x+n).

l_{x} = The number of persons living at the beginning of an age interval (x) out of an original cohort of 100,000.

$_{n}d_{x}$ = The number of persons who would die during an age interval (x to x+n) out of an original cohort of 100,000.

$_{n}L_{x}$ = The number of person-years that would be lived within an indicated age interval (x to x+n) out of an original cohort of 100,000 alive for all or part of the interval.

T_{x} = The number of person-years that would be lived after the beginning of an age interval (x) by an original cohort of 100,000 until all are assumed to have died.

$\mathring{e}_{x}$ = The average remaining lifetime (in years) for an individual person who survives to the beginning of an indicated age interval (x).

LIVE BIRTH-A live birth is the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy, which, after such separation, breathes or shows any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles.

LIVE-BIRTH ORDER-Order number is equal to number of previous live births plus current birth.

LOW-WEIGHT BIRTH-Birth wherein the birth weight is equivalent to 2,500 grams or less (approximately 5 lbs., 8 oz.).

MATERNAL DEATHS-Those deaths wherein the physician has designated a maternal condition as the underlying cause of death.

MEAN-The average of a set of values, equal to the sum of the values divided by the number of values.

MEDIAN-The central value of a distribution of values wherein the same percentage of observations are above this point as are below.

MINOR CIVIL DIVISION-City, Village, or Township.

NEONATAL DEATH-Death occurring to individual less than 28 days of age.

OCCURRENCE-Place where the event actually occurred.

PERINATAL DEATH-Fetal death or death under 1 week of age.

PROBABILITY OF EVENTUALLY DYING FROM A GIVEN CAUSE OF DEATH-The chance of death due to a given cause rather than some competitive cause over the course of a lifetime based on current mortality data and life expectancy techniques.

RACE-Race for mother, father, or decedent is as stated on certificate. Race of child is determined from the race of the parents.

REMAINING YEARS OF LIFE-A hypothetical calculation of the average number of years a cohort of persons will live given that they have reached a specific age and assuming they are subject to the age-specific mortality rates observed over a given time period.

RESIDENCE-Usual place of residence for person to whom event occurred. For births and fetal deaths residence is defined as the mother's usual place of residence.

TOTAL BIRTHS-Live Births and Fetal Deaths.

UNDERLYING CAUSE OF DEATH-That condition giving rise to the chain of events leading to death.

RATES AND RATIOS

AGE-ADJUSTED DEATH RATE-A summary rate of death that is developed using a standard population distribution to improve the comparability of rates for areas or population subgroups with differing age distributions. When calculated by the direct method, as in this report, age-specific death rates for a geographic area or population subgroup are multiplied by the standard population by specific age and the products summed and divided by the total standard population. Age-adjusted death rates represent the mortality experience that would have occurred in a standard population had the age-specific rates of the area or population subgroup been experienced by the standard population. These rates are presented as per 100,000 population.

AGE-SPECIFIC BIRTH RATE- No. of Resident Live Births to Women of a Specific Age divided by Total Female Population of Specific Age x 1,000.

AGE-SPECIFIC DEATH RATE-No. of Deaths in Specific Age Group divided by Total Resident Population in Specific Age Group x 100,000.

AGE-SPECIFIC DEATH RATE BY CAUSE OF DEATH-No. of Deaths in Specific Age Group and from a Specific Cause divided by Total Resident Population in Specific Age Group x 100,000.

AGE-SPECIFIC MARRIAGE RATE-No. of Marriages in Specific Age Group by Sex divided by Total Resident Population in Specific Age and Sex Group x 1,000.

CAUSE-SPECIFIC RATE-No. of Deaths due to a Specific Cause divided by Total Resident Population x 100,000.

COMMUNICABLE DISEASE CASE RATE-No. of Reported Cases (Specific Communicable Diseases) divided by Total Resident Population x 100,000.

CRUDE BIRTH RATE-No. of Resident Live Births divided by Total Resident Population x 1,000.

CRUDE DEATH RATE-No. of Resident Deaths divided by Total Resident Population x 1,000.

DIVORCE RATE-No. of Persons (Divorces and Annulments) divided by Total Resident Population x 1,000.

FERTILITY RATE-No. of Resident Live Births divided by Total Female Population (Ages 15 - 44) x 1,000.

FETAL DEATH RATE-No. of Resident Fetal Deaths divided by Total Resident Live Births and Resident Fetal Deaths x 1,000.

FETAL DEATH RATIO-No. of Resident Fetal Deaths divided by Total Resident Live Births x 1,000.

FIRST MARRIAGE RATE-No. of Marriages to Persons not Previously Married by Sex divided by Total Resident Population by Sex x 1,000.

INFANT MORTALITY RATE-No. of Infant Deaths divided by Total Resident Live Births x 1,000.

LOW-WEIGHT BIRTH RATIO-No. of Low-Weight Births divided by Total Resident Live Births x 1,000.

MARRIAGE RATE-No. of Persons Married divided by Total Resident Population x 1,000.

MATERNAL DEATH RATE-No. of Maternal Deaths divided by Total Resident Live Births x 10,000.

NEONATAL DEATH RATE-No. of Neonatal Deaths divided by Total Resident Live Births x 1,000.

NO PRENATAL CARE RATIO-No. of Live Births to Mothers With No Prenatal Care divided by Total Resident Live Births x 1,000.

PERINATAL DEATH RATE-No. of Perinatal Deaths divided by Total Resident Live Births and Resident Fetal Deaths x 1,000.

RATE OF NATURAL INCREASE-(Total Resident Live Births minus Total Resident Deaths) divided by Total Resident Population x 1,000.

TOTAL FERTILITY RATE-Sum of (Age-Specific Birth Rates) x (Number of Years in Age Group) for each Age Group from ages 10-14 through 45-49 years.

RELIABILITY OF RATES-Care should be taken in drawing specific inferences from comparisons of rates for different areas or different periods of time. Rates based on a small number of events or for a small area tend to exhibit considerable variation from time period to time period or place to place. Excessive variation in rates not only negates their utility as estimators of the probability of an event occurring but also their usefulness for comparative purposes. Also, one should recognize the limitations of using unadjusted rates in attempting to attribute rate differences to particular factors. For example, one should not attempt to state that there was a significant difference in rates for two geographic areas for atherosclerosis without first adjusting the rates to negate the effects of differing age distributions in the two areas. Many times there are simply not sufficient data available to adequately adjust rates for all possible compounding factors. For this reason, the reader should exercise diligence and caution while attempting to draw substantive conclusions when comparing vital statistics rates.

QUALIFICATIONS AND LIMITATIONS OF DATA AND CALCULATIONS

UNDERREGISTRATION OF EVENTS

The underregistration of vital events in Michigan is considered to be a minimal problem particularly for births and deaths. Tests of registration completeness conducted in conjunction with the 1950 Census indicate that the registration of births was 98.5 percent complete, and that death registration was even more complete. The number of certificates received too late for inclusion in annual statistical files is insignificant when examining statewide patterns.

GEOGRAPHIC ALLOCATION

The allocation of events on a residence or occurrence basis is for the most part accurate and complete. However, allocations to minor civil divisions are subject to question in some instances. In those cases where the respondent completes the residence item with a mailing address, geographic allocation is sometimes undeterminable and the record receives an unknown minor civil division code.

FETAL DEATHS

Fetal deaths in Michigan include only those conceptions that have passed through 20 weeks gestation or that weigh 400 grams or more. Prior to the introduction of a new reporting form for fetal deaths on September 30, 1978, Michigan law required only the reporting of deaths of fetuses which had passed through 20 weeks gestation Inadequacies in determining the gestational age of the fetus may have resulted in some underreporting of fetal deaths. The change in definition has had little impact in the number of fetal deaths reported.

COMPARABILITY IN CAUSE OF DEATH STATISTICS

The reader should bear in mind two major limitations in interpreting changes in cause-of-death statistics. Changes in nomenclature and the classification scheme (International Classification of Diseases) and changes in diagnostic practices may seriously affect the comparability of such statistics over time. The classification scheme (ICD) is modified approximately once every ten years to reflect changing medical opinion and practice. The reader is most accurate when comparing cause-of-death certificates which are coded via one revision of the International Classification of Diseases and utilizing the coding practices and procedures in effect at that time.

In order to compare cause-of-death statistics from one revision to the next it is necessary to apply a 'comparability ratio'. Such ratios are developed by comparing the number of deaths assigned to a certain condition or group of conditions under one revision to the number assigned under another revision of the ICD.

In 1979 the 9th Revision of the International Classification of Diseases was introduced for coding causes of death.

LIFE EXPECTANCY

The procedure used to obtain the Michigan life table values is called the iterative method. This is a method which has been developed by Professor Felix Moore of the Department of Biostatistics, School of Public Health, University of Michigan.

For the age group 0-1 the method utilizes the algorithm developed by Greville with no iteration. For all subsequent age groups the method of Greville (Keyfitz) is used with three iterations to improve the estimate of $_nd_x$ and $_nq_x$. An iteration procedure is also used for $_nL_x$ for age groups 75-80 and 80-85 where the accuracy of mortality information is a factor and for obtaining the separation factor for the age group 1-4.

Age-Adjustment Procedure and Population Estimation

The age-adjusted rates for Michigan presented in this report for years 1970-1979 were calculated using Michigan resident mortality data and a revised series of population estimates. Death records with the race not stated were first randomly allocated to the white and other than white groups based on the proportion of Michigan resident deaths in each of the racial categories for that year. Records with sex not stated were randomly assigned to male and female (50 percent each). Records with age not stated were allocated to the age group 85 and over.

The population of Michigan as of April 1, 1970 as enumerated by the U.S. Census Bureau was used for the 1970 population figure in this report. Michigan population estimates for each year from 1971-1979 were developed from projections by age and sex furnished by the Michigan Department of Management and Budget, Office of the Budget, and total population estimates prepared by the U.S. Census Bureau. Race estimates were prepared by the Michigan Department of Public Health, Office of Vital and Health Statistics, by projecting into the 1970's the mean annual rate of change in the race proportions of each age-sex group of the population observed between the 1960 and 1970 censuses.

When the 1980 census counts by race became available revised estimates of the 1979 population of white and other than white persons were calculated. A revised race breakdown of the original 1979 estimate of the total state population was prepared using a revised estimate of the proportion of the state population that was white in 1979. The revised proportion white for 1979 was calculated by interpolating between the proportions white observed in the 1970 and 1980 censuses. The revised estimate of the white population for 1979 was 7,855,431, or 1.1 percent lower than the original estimate of 7,938,823. For the other than white population the revised estimate of 1,351,569 for 1979 is 6.6 percent above the original estimate which was used in this report. Crude birth and death rates for the other than white population for 1979 presented in this report are thus 6.6 percent higher than would be rates based on the revised population estimate. For the white population the crude rates presented for 1979 are

1.1 percent lower than would be rates calculated with the revised population estimate. Since age-adjusted rates are dependent on the age structure of the population these "correction factors" are not strictly applicable to the age-adjusted death rates shown in this report.

In the age-adjustment procedure nineteen age groups were employed including under 1 year, 1-4 years, five year age groups from 5-9 years to age 80-84, and 85 years and over. Age-specific rates for the total population and for each subgroup were applied to the same standard population distributed by age. The resulting "expected deaths" were then summed over the nineteen age groups and divided by the total of the standard population to obtain the age-adjusted rate. The standard population selected was the 1940 United States enumerated population. Comparisons can be made between subgroup rates, between rates in different years, and between rates for Michigan and similarly computed rates for the United States. Rates for the United States were taken from publications by the National Center for Health Statistics, U.S. Dept. of Health and Human Services.

NATALITY

SECTION I

Natality: An Overview 1979

TOTAL RESIDENT BIRTHS	145,668
TOTAL RESIDENT LIVE BIRTHS	144,452
RESIDENT LIVE BIRTHS PER DAY	395.8
TOTAL RESIDENT FETAL DEATHS	1,216
RESIDENT FETAL DEATHS PER DAY	3.3
CRUDE BIRTH RATE	15.7
FERTILITY RATE	71.5
FETAL DEATH RATIO	8.4
FIRST ORDER BIRTHS (PERCENT OF TOTAL LIVE BIRTHS)	41.8
MEDIAN BIRTH WEIGHT IN GRAMS (LIVE BIRTHS)	3,374
MEDIAN BIRTH WEIGHT IN GRAMS (FETAL DEATHS)	1,332
LOW-WEIGHT LIVE BIRTHS	10,178
LOW-WEIGHT BIRTH RATIO	70.5
MEDIAN AGE OF MOTHER (LIVE BIRTHS)	24
MEDIAN AGE OF MOTHER (FETAL DEATHS)	24
LIVE BIRTHS WITH CONGENITAL ANOMALIES	1,228
CONGENITAL ANOMALIES PER 10,000 LIVE BIRTHS	85.0
LIVE BIRTHS WITH NO PRENATAL CARE	897
NO PRENATAL CARE RATIO	6.2
HOME BIRTHS	619
LIVE BORN SETS OF TWINS	1,444
LIVE BORN SETS OF TRIPLETS	20
LIVE BORN MULTIPLE BIRTHS OF FOUR OR MORE	0
MALE LIVE BIRTHS PER 100 FEMALE LIVE BIRTHS	105.4

Between 1900 and 1979 the number of total births has varied considerably. The general trend has been increasing numbers of total births from 1900 through 1957 and declining numbers since that time. According to the annual enumeration of births by local officials in 1900 there were 45,024 total births in Michigan. This figure dropped slightly to 44,722 in 1901 (the lowest total in the century). The number of total births reported increased significantly with the initiation in 1906 of mandatory filing of individual certificates for each Michigan birth. Total births increased during the next two decades, dropped temporarily in 1919, and then leveled off at just over 100,000 between 1924 and 1930. During the first years of the Great Depression, total births declined from 102,596 in 1930 to 83,258 in 1933. Then from 1933 to 1957, excluding the war years of 1944 and 1945, total births increased to a century high peak of 211,642 in 1957. Total births in the next two decades dropped to a post-World War II low of 132,649 in 1976. In each of the past three years, the number of total births increased. The number in 1979 was 145,668. (Table 1.1).

TABLE 1.1 - Total Births, Michigan Residents Selected Years, 1900-1979

YEAR	TOTAL BIRTHS
1900	45,024
1901	44,722
1910	66,668
1920	96,015
1930	102,596
1933	83,258
1940	101,708
1950	163,150
1957	211,642
1960	198,064
1970	173,727
1971	164,167
1972	148,624
1973	143,232
1974	138,865
1975	135,304
1976	132,649
1977	139,704
1978	140,023
1979	145,668

LIVE BIRTHS

Between 1900 and 1979, the number of live births has varied considerably. The smallest number of live births officially recorded in this century was 43,221 in 1901. The actual number of live births was undoubtedly higher, as a significant percentage of births were not recorded prior to 1906. Figure 1.1 portrays the number of live births for Michigan from 1900 through 1979. Live births, which constitute a large percentage of total births, naturally followed the same pattern of increases and decreases, rising appreciably from 43,699 in 1900 to 208,488 in 1957, the peak year for this century. Between 1957 and 1976, live births decreased by 37 percent to 131,378, the lowest total in 31 years. In 1977, however, live births increased by 5.4 percent, the largest such increase since 1951. The figure in 1978 was up slightly (0.3 percent), and in 1979 the live birth figure of 144,452 was 4.1 percent higher than that of 1978. This is the most live births since 1972.

The national pattern is similar to that observed in Michigan. Live births increased from an estimated 2,718,000 in 1909 to an estimated 4,300,000 in 1957. Since 1957, there has been a general decline in live births. The low point occurred in 1973 when live births in the United States totaled 3,136,965. The 1977 national live birth total was 5.0 percent higher than the 1976 figure, and the number for 1978 was up 0.2 percent. The provisional figure of 3,473,000 for 1979 is 4.2 percent higher than that of 1978.

Another view of the historic pattern in live births may be obtained through examination of changes in the crude birth rate. By considering population size the historic pattern of live births is stablized (Figure 1.2). The crude birth rate in Michigan ranges from a low of 14.4 in 1976 to a high of 27.4 in 1956. The crude birth rate increased from 22.1 in 1906, the first year for filing birth certificates, to 26.2 in 1916. During the period 1917 to 1933 Michigan's crude birth rate declined steadily, reaching 16.2. The birth rate rose over the next 23 years to a peak in 1956 (27.4). Since 1956, Michigan's crude birth rate has declined. In 1973, a century low rate was observed, replacing the 1933 rate as the lowest recorded for the state. The next three years, in succession,

FIGURE 1.1 Live Births, Michigan Residents, 1900-1979.

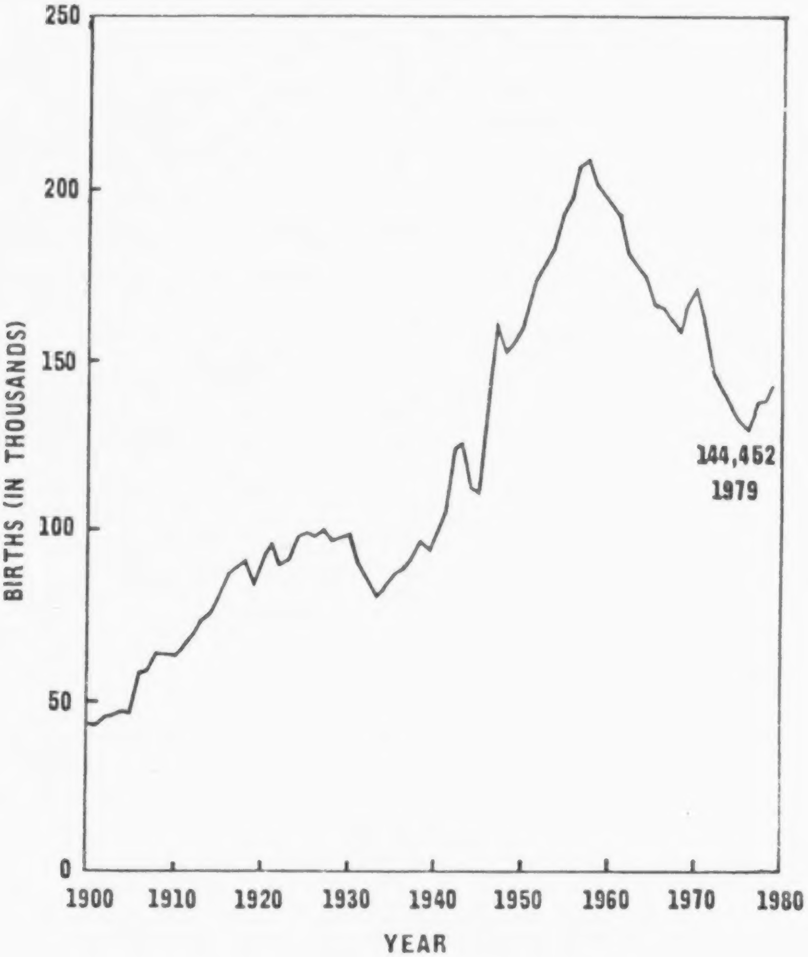

FIGURE 1.2 - Live Birth Rates, Michigan Residents, 1900-1979 and United States Residents[1] 1909-1979

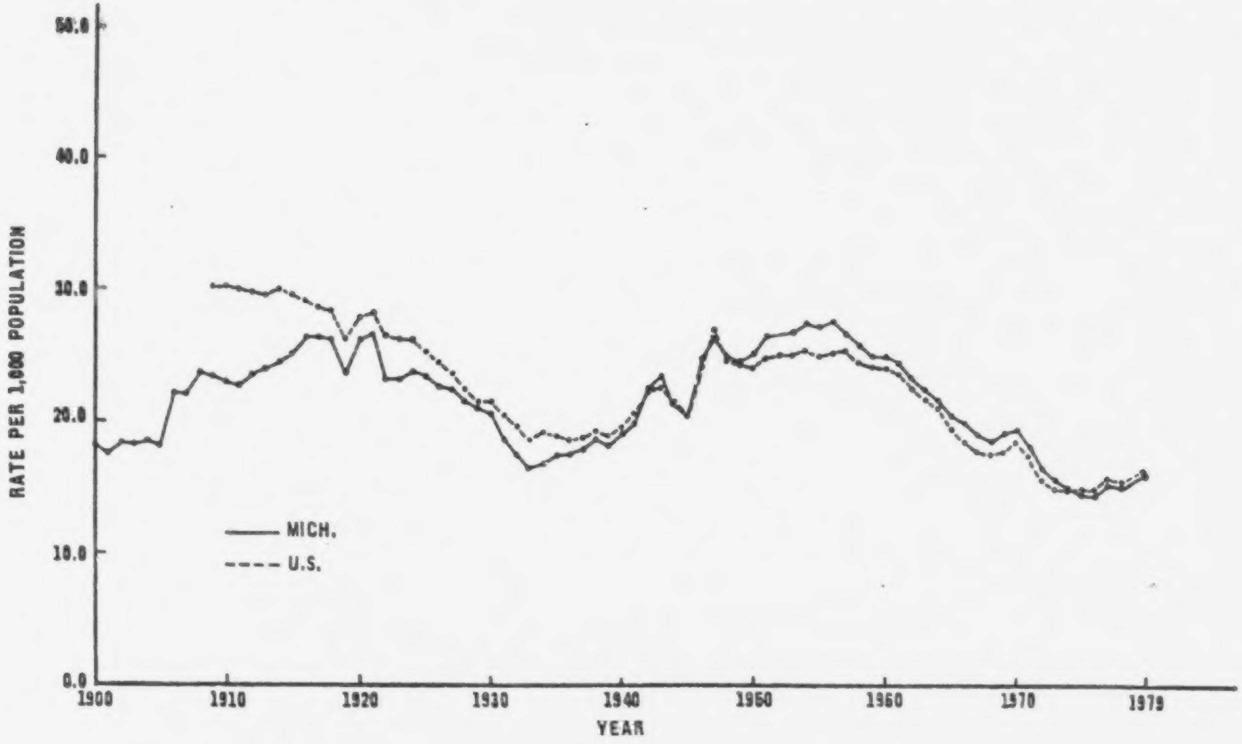

---

[1] .U.S. Rates Prior to 1909 are not Available; U.S. 1979 Figure is provisional

replaced the prior year figure as the lowest birth rate on record. In 1977, the crude birth rate increased to 15.2. The 5.6 percent increase in the crude birth rate in 1977 was the largest percentage increase in this rate since 1947. The crude birth rate declined slightly in 1978 to 15.1. In 1979 the crude birth rate increased by 4.0 percent to 15.7, the highest rate since 1972.

National statistics follow the same general pattern of rising and falling as observed in Michigan. The highest rate observed nationally over the period 1909 through 1979 was 30.1 in 1910, while the lowest was 14.8, occurring in both 1975 and 1976. United States' live birth rates were above those observed in Michigan without exception from 1909 to 1941. Between 1942 and 1947, national rates were above those for the state twice. National birth rates were below Michigan rates from 1948 through 1974. For the past five years the rate for the nation has been just above that observed in Michigan. In 1979 the provisional rate for the United States was 15.8 (Table 1.2).

TABLE 1.2 - Live Births and Crude Birth Rates, Michigan and United States Residents, Selected Years, 1900-1979

UNITED STATES			MICHIGAN	
LIVE BIRTHS	RATE	YEAR	LIVE BIRTHS	RATE
N/A	N/A	1900	43,699	18.1
2,777,000	30.1	1910	64,109	22.8

FERTILITY

The crude birth rates examined above are useful statistics for gauging overall trends in live births for specific geographic areas. Where attempts are made to interpret such trends, however, crude birth rates can be misleading. These rates do not incorporate specifically the size of the population capable of bearing children. This population subset, generally considered to be women between the ages of 15 through 44, does not always maintain a stable relationship with the total population. A measure for analyzing changing birth patterns that is more exact is the fertility rate. Since the fertility rate relates the number of live births to the female population of childbearing age, valid comparisons for various periods of time and various locations are possible.

A comparison of fertility rates for Michigan with those for the United States is presented in Table 1.3. Some interesting contrasts can be seen between fertility rates and the crude birth rates as presented in Table 1.2. In both the state and the nation the crude birth rates dropped between the years 1950 and 1960 while the fertility rates increased between these two years. While Michigan's crude birth rate was below the United States' rate between 1975 and 1979, the state's fertility rate was higher than the national rate.

These differences point to the importance of the fertility rate in making comparisons and drawing conclusions. The crude birth rate changes observed understate the recent decline in fecundity for both regions. Since 1960 the crude birth rate in Michigan has dropped 36.9 percent, while the fertility rate in 1979 was 41.9 percent below the 1960 rate. For the United States over this same period the crude birth rate declined 33.3 percent and the fertility rate fell by 42.4 percent. The proportion of the population in the childbearing ages has increased over this 19 year period.

Figure 1.3 displays the changes in the total fertility rate between 1920 and 1979 for Michigan and the United States. The total fertility rate is a hypothetical measure of the number of live births that would occur to each 1,000 women during their reproductive life, if these women experienced the age-specific birth rates observed in a given year. Michigan's total fertility rate has generally paralleled that of the nation. The Michigan rate dropped from 3,195.5 in 1920 to 2,006.5 in 1933 and then increased between 1933 and 1957, reaching 4,100.0 in the latter year. Since 1957, the total fertility rate in Michigan has declined

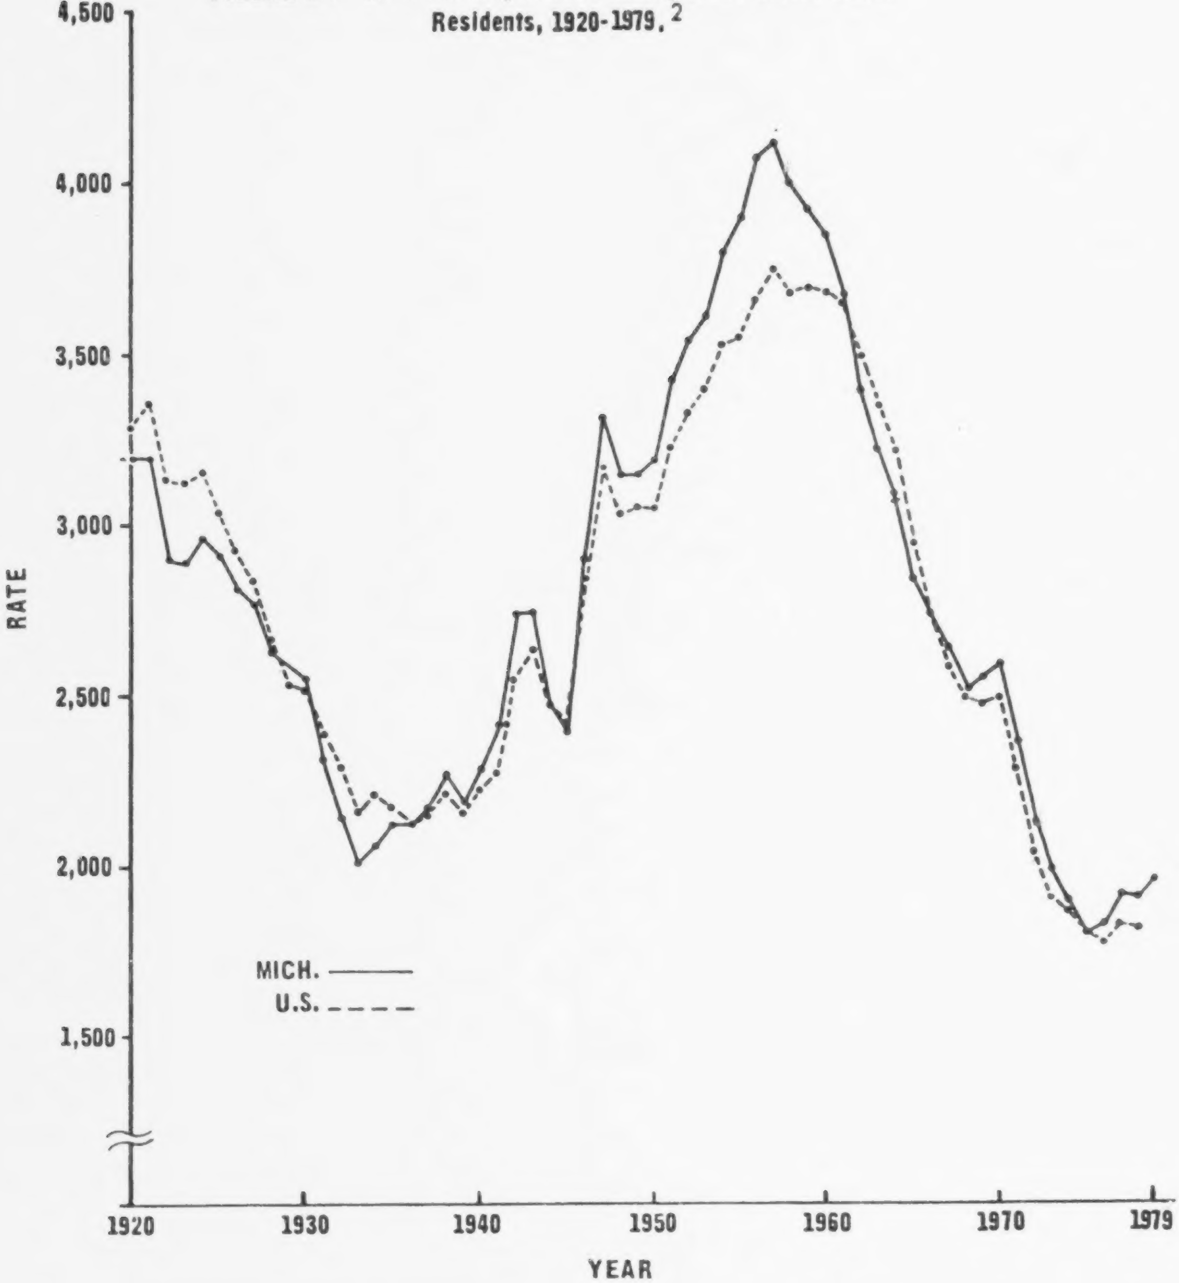
FIGURE 1.3 Total Fertility Rates,[1] Michigan and United States Residents, 1920-1979.[2]



[1] Total Fertility Rate is total children to 1,000 Women in their lifetime Assuming Constant Live Birth Rates.

[2] 1979 Data for U.S. not available.

to a low of 1,798.5 in 1975. Between 1975 and 1979 the total fertility rate for Michigan increased by 8.6 percent. The rate was 1,954.0 in 1979 for Michigan and 1,800.2 in 1978 for the nation.

Since 1973 both Michigan and national total fertility rates have been below 2,000. A total fertility rate of over 2,000 is necessary for replacement of the parents since not all women survive the reproductive years nor do all children survive to adulthood. If the total fertility rate falls below 2,000 for a long period, a natural decrease in population will eventually result. It should be noted that although the total fertility rate has been below 2,000 since 1973 the population of Michigan has not declined. Over the period 1973 through 1979 there were 438,558 persons added to the population of Michigan through the excess of births over deaths!

Zero population growth means that the numbers of deaths and live births are equal so that, apart from migration, the population remains constant. To achieve zero population growth in the short run the birth rate would have to decline by 49 percent or the death rate increase by 96 percent or some combination of those changes must occur.

RACIAL COMPOSITION

In the period 1970 through 1979, the racial composition of live births in Michigan changed. Live births of white persons declined from 83.8 percent of all live births in 1970 to 82.2 percent in 1979. Live births of black persons increased from 15.7 percent of the total in 1970 to 16.6 percent in 1979. Live births of all other races increased from 0.4 percent in 1970 to 1.1 percent in 1979. It should be noted that Indians from India were classified as white before 1978 and among other races in 1978 and 1979. In absolute terms, the numbers of births of black and white infants declined between 1970 and 1976, with an especially sharp decline observed in births of white infants between 1970 and 1972. Since 1976 the number of live births of white and black infants increased by 8.2 percent and 7.4 percent respectively. The number of live births of American Indians and Filipinos increased between 1970 and 1979, as did those in the category of other races (Table 1.4).

Table 1.5 provides a comparison between crude birth rates and fertility rates for whites and other races in Michigan during the decade of the seventies. In 1970 the crude birth rate for other than white persons was 44.6 percent above that for whites. By 1973, this percentage had increased to 62.1 percent. In 1974, the percent dropped sharply to 48.2, and by 1979 it had fallen to 35.6. Paralleling the trends in numbers of live births, the crude birth rates for both groups declined, reaching a low in 1976 and increasing since then. The crude birth rate for white persons in 1979 was 19.0 percent below that observed in 1970 while the rate for the other than white group was 24.1 percent below the rate for 1970. The birth rate in 1979 for white persons was 3.5 percent higher than the rate for 1978, while the increase for persons of other races was slightly less at 3.1 percent.

The fertility rates contained in Table 1.5 reveal that there are important differences in population structure for white persons compared to those of other races. By comparing live births to the respective numbers of women aged 15-44 for these two groups, the relative differences in rates decrease. The fertility rate for other than white persons was 33.1 percent above the rate for white persons in 1970 and 22.6 percent

14.9	69.0	1979	20.2	84.6

---

[1] Births of unknown race are excluded.

higher in 1979. Since 1970 the fertility rate for other than white persons has declined 27.8 percent compared with a 21.6 percent drop for white persons. In 1979 the fertility rate for other than white persons increased by 1.2 percent from the rate observed in 1978 while the rate for white persons increased by 2.4 percent.

AGE OF MOTHER

In 1979 50.5 percent of all live births were to women less than 25 years of age. Only 0.5 percent occurred to women 40 or more years of age. The median age of mothers was 24 years. Mothers of other than white infants were younger (median 23 years) than mothers of white children (median 25 years). Approximately 60 percent of the other than white infants were born to women aged 24 or less compared to 48.5 percent of the white infants. This differential is the result of the relatively large percentage of other than white live births to women at ages 15-19 (Table 1.6).

The total number of live births declined by 15.9 percent between 1970 and 1979 (Table 1.7). The largest relative declines occurred in the age groups over 34 and under 20. The age group 20-24 also experienced a decline (22.1 percent) greater than that for women of all ages. The number of live births to women 25-29 was essentially the same in 1979 as in 1970, while there was a 5.1 percent increase in live births to women 30-34 years of age over the decade.

Table 1.7 also provides the age distribution of the childbearing population in 1970 and 1979. Examination of the table shows that the declines in numbers of live births for most age groups occurred despite an increase over the decade in the number of women within those age groups. The largest increase in population occurred in the age group 30-34, the only age group having more live births in 1979 than in 1970. The only group to experience a population decline (28.1 percent) was the 40-44 year age group.

AGE-SPECIFIC LIVE BIRTH RATES

As displayed in Table 1.8, a substantial reduction in the age-specific birth rates for Michigan females across all age groups has occurred since 1970. The greatest relative decrease in birth rates between 1970 and 1979 was for women over 34 years of age. Birth rates for women under 25 and for women 30-34 also declined more than did the birth rate for women of all ages. The decline in the birth rate for women 25-29 years old was 10.3 percent, the smallest decrease observed for any age interval.

Figure 1.4 displays age-specific live birth rates for the period 1970-1979. Birth rates in all age groups dropped during the first half of the decade. For women under 20 and for women over 34 years the birth rates declined consistently throughout the decade,

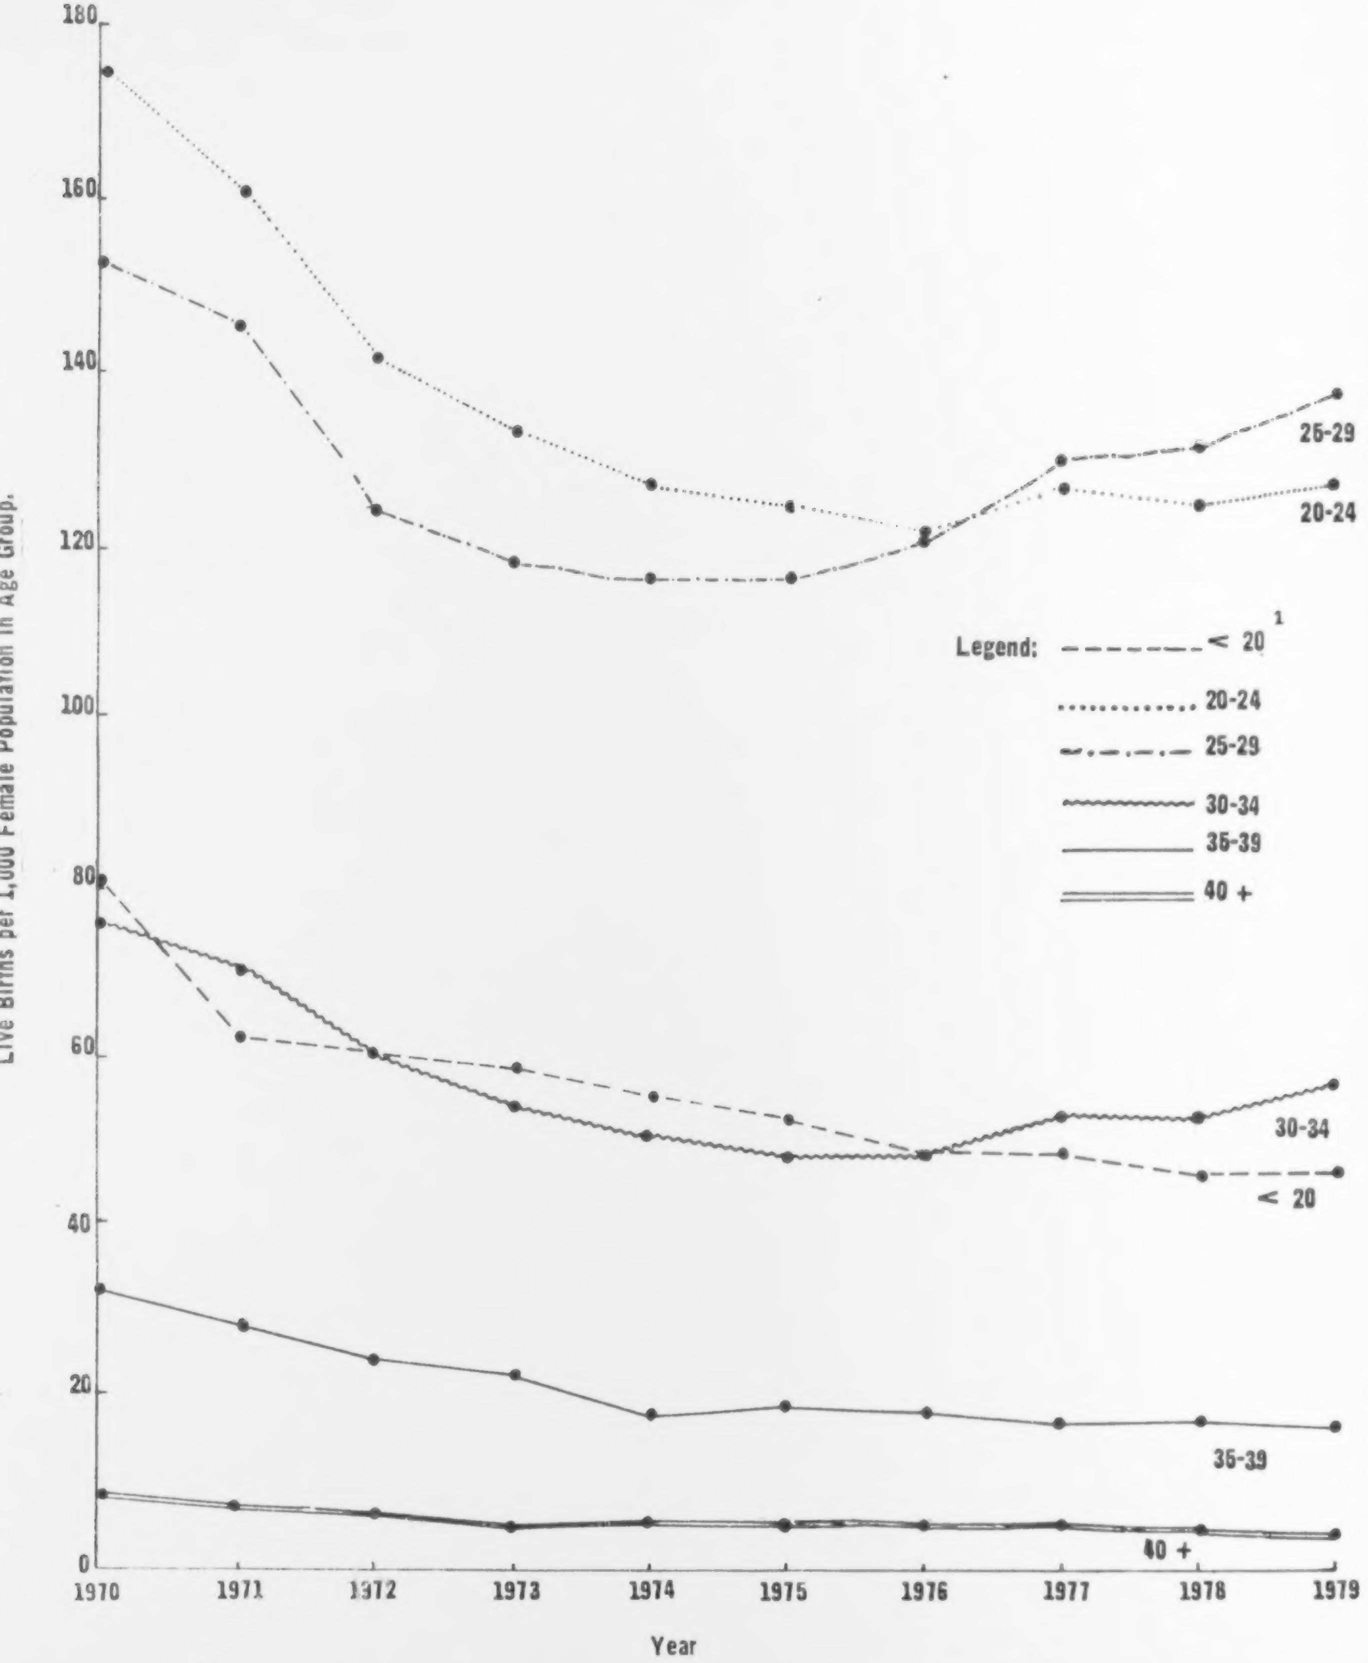
FIGURE 1.4 Age-Specific Live Birth Rates,
Michigan Residents , 1970-1979



---

[1] Based on live births to women under 20 and population of females 15-19.

with the largest declines occurring early in the decade. Birth rates for women between 25 and 34 have increased since 1975. The birth rate for the 20-24 year age group also increased during the latter part of the decade, although the increase was smaller.

In 1970, women aged 20-24 had the highest birth rate of any age group, 14.3 percent higher than that of women aged 25-29. Since 1977 the birth rate of women in the 25-29 year age group has surpassed that of women aged 20-24. In 1979 the birth rate for the 25-29 year age group was 8.0 percent higher (Table 4.4).

Table 1.8 displays age-specific live birth rates for white women and women of all other races for the years 1970 and 1979. Generally, rates for other than white women were above those for white women. The exception to this is the age group 25-29. In both 1970 and 1979 the live birth rate for other than white women in this age group was slightly below that for white women. Live birth rates declined over these nine years across all ages for both racial categories. The largest relative decreases in these rates were experienced by women of both racial groups who were 35 years or older and by other than white women under 20 years of age. The smallest declines were for women aged 25-29, with the rate for white women in this age group dropping by 11.5 percent and that for other than white women falling by 2.1 percent.

BIRTH ORDER

The percent of live births which are first order births is displayed in Figure 1.5 for Michigan and the United States for the period since 1960. Between 1960 and 1970, the percent of first order births increased from 22.9 to 37.4 in Michigan and by 1979 the percent had increased to 41.8. However, the number of first births declined by 15.9 percent between 1970 and 1976 (Table 1.9). Since 1976 the number of first births has increased 11.9 percent. The trend in first births has been similar for the United States.

The distribution of Michigan resident live births by live birth order is displayed in Tables 1.10 and 1.11 for the years 1970 and 1979. There has been a considerable shift in recent years toward smaller families. First and second order live births comprised 64.7 percent of all live births in 1970 and 74.1 percent in 1979. On the other hand, 18.8 percent of all live births in 1970 were fourth or higher order live births. In 1979 the figure was 9.3 percent. The greatest relative decline occurred in fifth or higher order live births. These constituted 10.1 percent of all live births in 1970 compared to 3.7 percent in 1979.

Within each age group first and second order births comprised a greater percent of all births in 1979 than in 1970, with the more pronounced shifts occurring in the age groups of older women. For women 30-39 years of age first and second order births comprised 21.3 percent of all births in 1970 and 45.8 percent in 1979. In 1979 30.5 percent of all live births to women 25-29 years of age were first births, compared to 19.5 percent at the beginning of the decade.

The median age of mothers having their first child increased from 21 to 22 between 1970 and 1979. For mothers having their second child, the median age increased from 23 to 25. The median ages for mothers having their third or fourth child each increased by one year between 1970 and 1979.

First births to women 25 years of age or older comprised 17.2 percent of all first births in 1970 and 30.4 percent in 1979. Similarly, second order births to women 25 years or older increased from 38.1 percent of all second order births in 1970 to 52.8

percent in 1979. This change in mother's age at birth is reflective of the emergence since 1977 of the 25-29 age group as the group with the highest age-specific birth rate (Table 1.8).

INTERPREGNANCY TIME PERIOD

In 1970 50 percent of all live births to women with prior terminations were reported as being spaced at least 2 years and 7 months apart. By 1975 the median time span had increased to 2 years and 9 months. In 1976 and 1977 the median value was unchanged. In 1978 the median fell to 2 years and 8 months and for 1979 the median was 2 years and 7 months. This trend is reflective of the changes in age-specific live birth rates of women between the ages of 20 and 34 (see Figure 1.4).

Although the median time span in 1979 is the same as that in 1970, there has been a shift in the distribution of birth spacings over the decade (Table 1.12). Most striking is the increase in relative frequency of births occurring five or more years after termination of the most recent prior pregnancy. In 1970 16.1 percent of women with prior terminations reported this spacing, while in 1979 the percent was 17.9. The other intervals of birth spacings all declined in relative frequency.

In 1979 women having live births whose most recent prior termination was a fetal death had a median time span of 1 year and 9 months between their previous termination and a live birth (Table 1.13). This compares to a median of 2 years 9 months for prior live births. Although 1 to 2 years was the modal time span for both groups, the percent of women with prior fetal deaths in this interval (47.3) was much larger than that for women with prior live births (27.5). The greatest relative difference was associated with time spans of less than one year. A spacing of less than one year was observed for 11.9 percent of all women reporting their most recent prior pregnancy as a fetal death. This compares to 1.7 percent of all women reporting their most recent prior pregnancy as a live birth.

[1] Terminations with time spans of zero years (i.e., second or later births in plural deliveries) and terminations with unknown time spans are excluded.

[2] Fetal death, as defined for the pregnancy history on the birth record, is a fetal death of any gestational age.

PRENATAL CARE

For 55,608 women delivering live born infants in 1979, prenatal care was initiated in the second month of pregnancy. This is 38.5 percent of all women having live births. The most common number of prenatal visits was twelve, and 57.4 percent of all live births were to women receiving 10-14 prenatal visits. Table 1.14 indicates the relationship between the month of pregnancy prenatal care began and the number of prenatal visits. For births in which the mother began receiving care in the first or second month, the median number of visits was 12. The median number of visits is lower as prenatal care begins later.

A total of 111,250 women (77.0 percent) having live births in 1979 started their prenatal care prior to the fourth month of pregnancy. This is slightly higher than the 75.3 percent figure recorded in 1978. The percent of women receiving care prior to the fourth month has increased steadily since 1970 when the figure was 69.0 (Figure 1.6).

There were also small but steady increases in the percent of women receiving care prior to the sixth month of pregnancy over the period 1970-1975. In 1970, 86.0 percent of women delivering live born infants received care prior to the sixth month of pregnancy. By 1975, this had risen to 91.6 percent. The figure remained at that level through 1978 (91.4 percent). In 1979 the figure increased to 92.1 percent.

The time prenatal care began varied with live birth order (Table 1.15). The percent of women who began care during the first trimester was highest for second order live births (79.9) and lowest for fifth or higher order births (62.9). Conversely, the percent of women who began care during the third trimester, or received no care, was lowest (2.6 percent) for second order live births. This figure increased with the number of previous live births. Among women with four or more previous live births, 6.7 percent had received no care by the beginning of the 7th month of the pregnancy.

The percent of mothers having ten or more prenatal visits was 68.3 in 1979, compared to 65.3 percent in 1978. This statistic varied considerable by race. While 71.2 percent of mothers of white infants had at least ten prenatal visits, only 55.1 percent of mothers of other than white infants had that many visits (Table 1.16). The median number of prenatal visits was 11 for mothers of white children and 10 for mothers of other than white children

(excluding those having an unknown number of visits). The mean number of prenatal visits was 11.0 for mothers of white infants, 11.1 percent higher than the mean of 9.9 visits for mothers of infants of other races.

In 1979, 897 resident live births or 6.2 of every 1,000 live births occurred with the mother having had no prenatal care. This figure includes only those where it was specified that the mother received no prenatal care. The comparative statistic was 6.4 in 1978 and 12.3 in 1971. Those who received no prenatal care were for the most part younger mothers (median age of 21). Also, the lack of prenatal care is disproportionately high among mothers of other than white infants. The ratio of live births in which the mother received no prenatal care to the total number of live births was 4.3 times as large for other than white infants as for white infants in 1979 (Table 1.17). For other than white infants this rate increased between 1978 and 1979 (14.0 to 16.8), while for white infants it declined (4.8 to 3.9).

[1] Ratio per 1,000 live births. Ratio denominator obtained from Table 1.6

BIRTH WEIGHT

The mean weight for all live births was 3,351 grams or approximately 7 pounds 6 ounces. The median weight was 3,374 grams or about 7 pounds 7 ounces (Table 1.18).

A subgroup of major importance when analyzing birth weight trends is the infant weighing 2,500 grams or less (approximately 5 pounds 8 ounces or less) at birth. Such infants have historically experienced higher mortality in their first year of life than heavier infants. In 1979, approximately 71 of every 1,000 live births weighed 2,500 grams or less (Table 1.19).

The proportion of low birth weight infants varies with the race of the child, the age of the mother, and the amount of prenatal care the mother has received. Note that these three factors are interrelated. Very young mothers and mothers who are not white have fewer prenatal visits; women whose race is not white have higher birth rates in the younger age groups, etc. Tables 1.19 and 1.20 present data on these three variables with respect to birth weight.

The age group with the highest low birth weight ratio (140.8) was the group of mothers under 15 years of age. This ratio was lower for each succeeding age group through age group 25-29 (60.4) then increased for the older age groups to 113.8 for mothers 40 years or older (Table 1.19).

When low birth weight ratios are examined by the number of the mother's prenatal visits even more striking variations are evident. The low birth weight ratio for the highest risk group was 7.2 times that of the group with the lowest ratio. The low birth weight ratio was highest when the mother had no prenatal care (265.3). The ratio declined as the number of prenatal visits increased through 15-19 visits, where the ratio was 36.9. The low birth weight ratio was 57.0 for mothers with 20 or more prenatal visits. It is likely that a very high number of prenatal visits is associated with problems in the pregnancy (Table 1.20). For low birth weight infants the median number of the mothers' prenatal visits was 9, compared to 11 for all infants. The mean number of visits for mothers of low birth weight infants was 8.8, 17.8 percent less than the mean of 10.7 for mothers of all infants. As low birth weight infants are more likely to have been born prematurely, the shorter prenatal period results in a reduction of the potential length of time for prenatal care.

[2] Ratio denominator obtained from Table 1.6

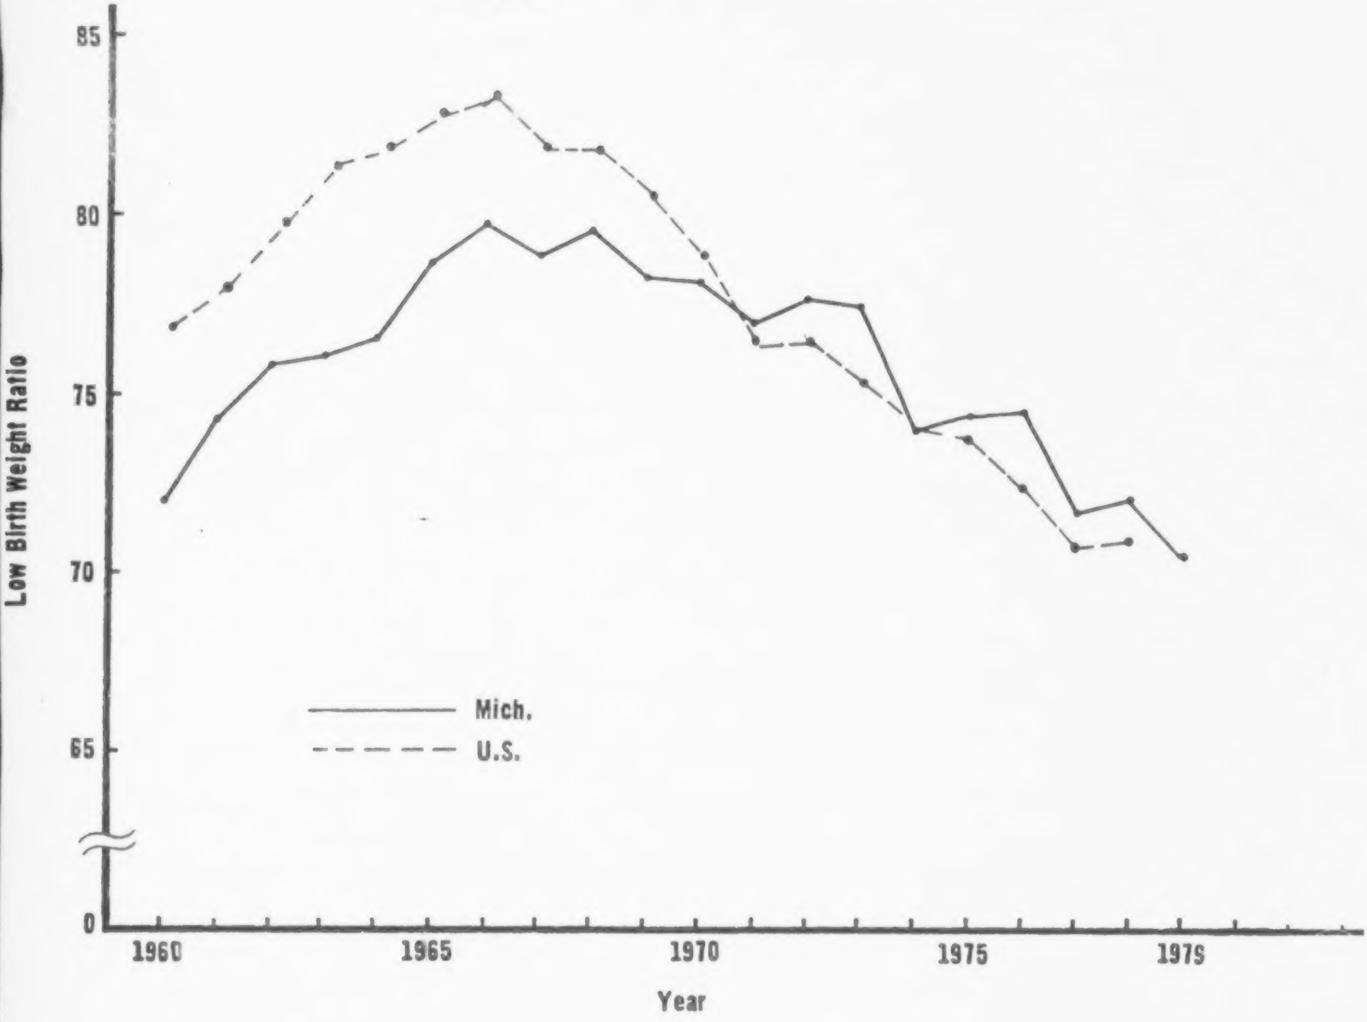
Other than white infants have a substantially lower mean and median birth weight than white infants (Table 1.18). The low birth weight ratio for other than white infants is 130.4 compared with 57.6 for white infants (Table 1.20). Other than white infants and white infants show similar patterns of rising and falling ratios varying with changes in the age of the mother and frequency of prenatal visits. The low birth weight ratio for other than white infants varied from a high of 312.4 where the mother had no care to a low of 73.7 where the mother had 15-19 visits. The ratio for white infants varied from a high of 222.7 where the mother had no care to a low of 30.5 where the mother had 15-19 prenatal visits (Table 1.20). Overall, the low birth weight ratio for other than white infants was 2.3 times the ratio for white infants. This is associated with a differential in the proportion of mothers having had fewer than 10 prenatal visits. While 25.8 percent of mothers having white infants had less than 10 prenatal visits, the corresponding figure for mothers having other than white infants was 39.1 percent (Table 1.16).

Examination of Table 1.19 reveals that although the low birth weight ratios for white and other than white infants exhibit a similar pattern of variation by age of mother, the ratios for other than white infants vary less. For white infants the ratio associated with mothers under 15 years of age (131.1) is over twice as great as that of mothers in the 25-29 year age group (50.9). For other than white infants this differential is less than 25 percent (145.9 for mothers under 15 vs. 118.0 for mothers 30-39). The ratios for white and other than white infants are similar for mothers under age 15 and for those age 40 or over.

Figure 1.7 displays the low birth weight ratio for Michigan and the United States over the last twenty years. In 1960 this ratio was 72.0 for Michigan. Between 1960 and 1966 the ratio increased, reaching a high for the 20 year period in 1966 (79.8). Since that time the ratio has generally declined. The ratio of 70.5 for 1979 is the lowest ratio in this time period. The pattern for the United States has been similar. The ratio increased from 76.9 in 1960 to 83.3 in 1966, and has since declined. In 1978 the low birth weight ratio for the nation was 70.9. The ratio for the United States was above that for Michigan each year from 1960 through 1970. Since then the ratio for the nation has been the same or lower than that of Michigan.

FIGURE 1.7 Low Birth Weight Ratio, Michigan and United States Residents, 1960-1979.[1]



---

[1] 1979 data for U.S. not available.

SEX OF INFANT

In 1979 51.3 percent of the infants born to Michigan residents were male. The proportion of males to females varies by race. The number of males per 1,000 females was 1,057 for white infants, 1,039 for blacks, 1,033 for American Indians, and 1,007 for infants of all other races (Table 1.21). For each race the low birthweight ratio for females is higher than for males. The ratio of 76.3 for females of all races is 17.7 percent above the corresponding ratio of 64.8 for males.

MOTHER'S EDUCATION

Educational attainment of women having live births in 1979 varied with their age (Table 1.22). Of all Michigan resident live births in 1979 21.9 percent were to women who had not completed high school. The majority (62.3 percent) of mothers aged less than 20 had not completed high school. The percent of mothers with fewer than 4 years of high school dropped to 21.3 for those aged 20-24 and to 9.6 for mothers aged 25-34. This percent increased to 15.5 for mothers aged 35-39 and to 24.6 for mothers 40 years or older. Conversely, age of mother varied with the level of education. The median age of the mother was lowest (20 years) for those with 9 to 11 years of education and highest (29 years) for women with 4 or more years of college.

Birth order varies with the mother's education as well as her age. Table 1.23 indicates that although the median age of mothers increases with educational level, the first birth ratio (first live births per 100 live births) also varies directly with educational attainment. The first birth ratio for mothers with 4 years of college was 46.1 compared to 36.3 for mothers with 8 or fewer years of education. Within each age group there are increases in the first birth ratio as educational level rises beyond the category of 9-11 years of education. For live births to women 20-24 years of age who had completed 4 or more years of college, 84.3 percent were to women with no previous live births, while only 24.4 percent of the live births to women of the same age who had not completed high school were first births. Mothers with 9 to 11 years of education had the lowest or second lowest first birth ratio within each age interval taken separately but the second highest total first birth ratio (43.7). This overall high ratio reflects the fact that a relatively large proportion of births to mothers with 9 to 11 years of education occurred before the age of 20.

[1] First live births per 100 live births. Births where the mother's age and/or education are not stated are included in the total but are not reallocated to specific age and education categories.

CONGENITAL ANOMALIES

One or more congenital anomalies were reported for 1,228 of the 144,452 resident live births in 1979 (Table 1.24). This translates to a rate of 85.0 per 10,000 live births.

In 1979 the 9th Revision of the International Classification of Diseases was introduced for the coding of reported congenital anomalies. Care should be exercised in making comparisons between the reported incidences of specific types of anomalies for years during which different revisions of the ICD were used to classify anomalies. In addition the frequency of reporting of specific anomalies is affected by the reporting schedule. Many conditions may not be apparent at the time the birth certificate is completed and filed.

The most frequently reported categories were ICD 754, certain congenital musculoskeletal deformities (including clubfoot), and ICD 755, other congenital anomalies of limbs (excluding those classified to 754), with 179 and 307 anomalies, respectively. When these categories are combined with the category 756, other congenital musculoskeletal anomalies, the total number of musculoskeletal system anomalies reported increases to 551, or 38.2 percent of all anomalies reported. There were 145 infants born with cleft palate and/or cleft lip.

Congenital anomaly rates by age of mother and race of child are presented in Table 1.25. The highest rates were experienced by mothers under 15 years of age (140.8 per 10,000 live births) and those over 39 years of age (145.5). The rate for the highest risk category, women 40 years or over, was nearly double the rate of the age group with the lowest rate, (75.1 for women 30-34 years). Congenital anomaly rates for white infants and infants of other races showed similar patterns of variation by age of mother, and the overall rates were similar (85.7 for white infants compared to 81.7 for infants of all other races).

Figure 1.8 displays the rate of reported congenital anomalies for Michigan resident live births over the period 1970-1979. The rate rose from 88.3 per ten thousand live births in 1970 to 100.8 in 1973. Since 1973 the rate has declined by 15.7 percent. The rate of 85.0 for 1979 is the lowest of the decade.

TABLE 1.24 - Congenital Anomalies[1] Reported by Type of Anomaly, Michigan Residents, 1979

Type of Anomaly	ICD[3] Number	Number of Conditions[4]	Rate per 10,000 Live Births
Other congenital anomalies of limbs	755	307	21.3
Certain congenital musculoskeletal deformities	754	179	12.4

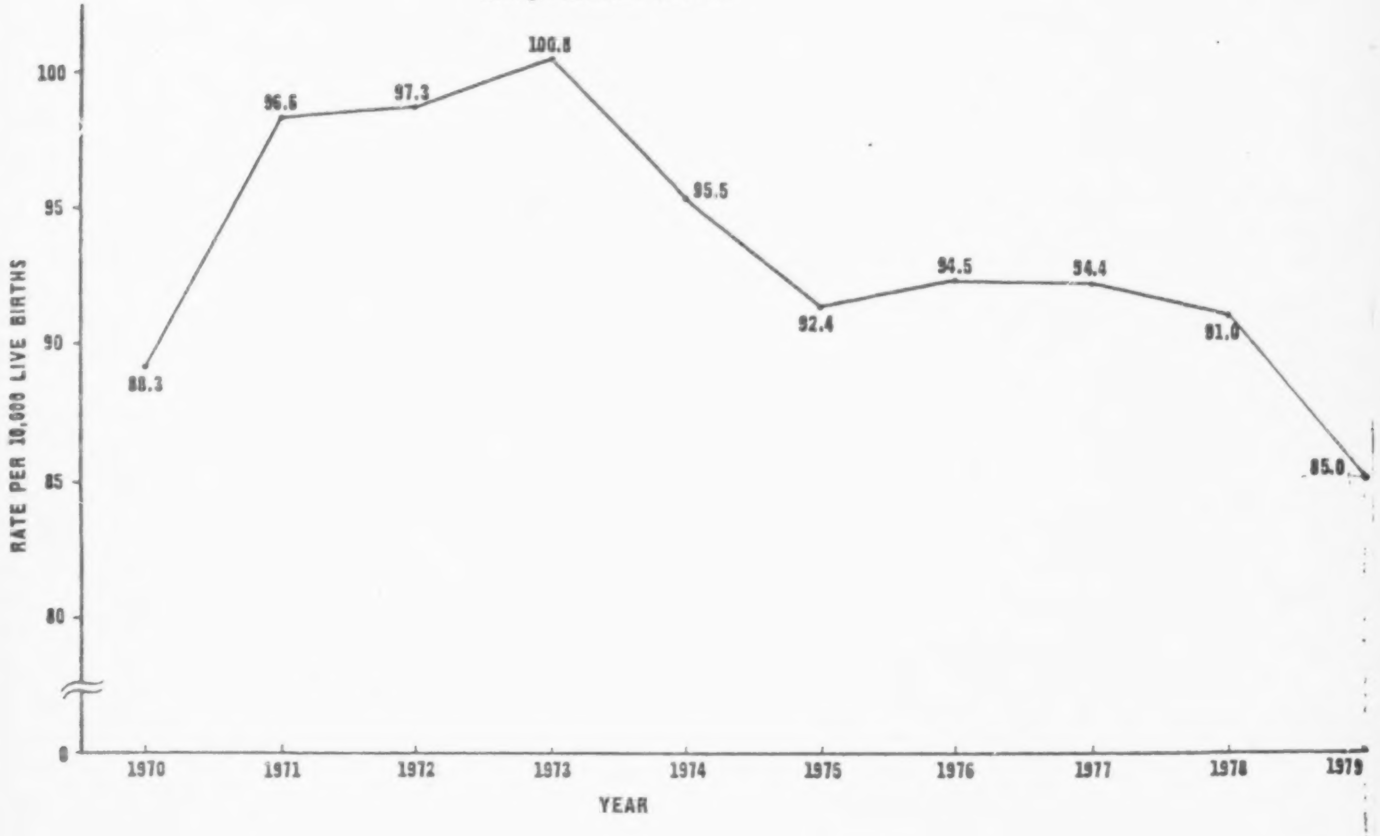
Michigan Residents 1970-1979



COMPLICATIONS

The numbers of deliveries with specific types of complications reported are shown in Table 1.26. These data represent entries in three boxes on the live birth certificate: complications of pregnancy, concurrent illnesses or conditions affecting this pregnancy, and complications of labor and/or delivery. It is important to note that these items are under-reported on the birth certificate. Some conditions or procedures, such as obstetrical operations, may be routinely performed by some physicians, and hence not be considered "complications". In addition to valid complications there are also inappropriate terms entered, such as "prematurity", "spontaneous delivery", or "home delivery". These inappropriate terms were omitted in the tabulations of complications shown in Tables 1.26 and 1.27. The total number of deliveries with entries in one or more of the three "complication" boxes was 36,255. Of these, 33,931 (93.6 percent) had one or more valid complications. This is a rate of 23.5 per 100 live births.

It should be noted that in some cases the code used to describe the complication is dependent on the box in which the entry is found, while in other cases the same code is given regardless of the box used. An example of the latter situation is chronic hypertension, which is shown in Table 1.26 under the heading "Concurrent illnesses or conditions affecting this pregnancy" regardless of the box in which it was entered on the birth certificate. Thus, there were 6,831 deliveries (472.9 per 10,000 live births) with one or more entries which were coded to the various categories under the heading "Concurrent illnesses or conditions affecting this pregnancy", while the number of births with one or more entries in the box bearing this title on the birth certificate was only 4,808 (332.8 per 10,000 live births). This latter figure is comparable to the rate of 308.2 reported for 1978 as prior to 1979 specific types of complications were not coded and tabulated. Rates presented for "Concurrent illnesses or conditions affecting this pregnancy", Complications of pregnancy", and "Complications of Labor and/or Delivery" were derived from the numbers of records with entries in these boxes.

Among the most commonly reported maternal conditions not directly related to the pregnancy were chronic hypertensive disease, diabetes mellitus, and previous cesarean

Table 1.26 - Live Births With Specific Types of Complications Reported, Michigan Residents, 1979

Type of Complication	Number of Deliveries[1]	Rate per 10,000 Live Births
Concurrent illnesses or conditions affecting this pregnancy	6,831	472.9
Chronic circulatory and genitourinary diseases in mother	1,611	111.5

At least one complication	33,931	2,348.9

---

[1] Sum of subcategories may not equal total for category due to the occurrences of multiple complications.

sections, which were reported 1,072, 799, and 2,239 times, respectively, in 1979. Toxemia of pregnancy was reported for 2,217 deliveries (153.5 per 10,000). The most common form was pre-eclampsia of pregnancy, which was reported 103.0 times per 10,000 deliveries. Various forms of difficult labor were reported in 10,790 deliveries (747.0 per 10,000). There were 1,643 deliveries complicated by conditions of the placenta and fetal membranes, and 2,824 by conditions of the umbilical cord. Premature rupture of membranes was reported for 3,364 deliveries. There were 13,048 deliveries reported as Cesarean sections. It should be noted that the type of delivery is not a question on the birth certificate, so that the rate of 903.3 Cesarean sections per 10,000 deliveries undoubtedly understates the true rate.

The distribution by age of mother and race of infant for deliveries with complications reported is shown in Table 1.27. Mothers less than 15 years of age and older mothers were more likely to experience complications. The lowest rate was for mothers 15-19 years of age (22.5 complications per 100 live births). The rate increased to 30.6 for mothers 40 years or over. The median age of mothers with complications reported was 25 years, compared to 24 years for all live births. A similar pattern of variation by age of mother was observed for white and other than white infants. The rate for other than white infants is higher than for white infants in all age groups except the age group under 15 years. Overall the rate for other than white infants is about 20 percent higher (27.2 compared to 22.7).

PLACE OF OCCURRENCE

Of some confusion to persons not familiar with vital records data is the difference between occurrence and residence figures. Information on events to residents of Michigan that occur throughout the country and, in some instances, outside its boundaries is collected in order to obtain the full scope of activity for the state population. Of the total 144,452 resident live births, 1,807 occurred outside the state. Information on these events is forwarded to the state of Michigan for statistical purposes only. While only 1.3 percent of the total for the state is involved, statistics for the counties on Michigan's southern and northwestern borders would be strongly affected were this information not available.

Table 1.28 shows the four major geographic areas where Michigan resident live births occur outside the state. These four border areas comprise 91.6 percent of all resident live births that occurred out of state. Live births to Michigan residents occurred in 36 of the 50 states in 1979 and in the District of Columbia.

The number of nonresident live births that occurred in Michigan in 1979 was 595. Information about those events was shared with the appropriate states by the State of Michigan under specific confidentiality guidelines, so that they might have a complete statistical file on their residents. The border areas comprised 77.0 percent of these events, as shown in Table 1.28. There were live births in Michigan to residents of 32 states and at least four foreign countries.

TABLE 1.28 - Michigan Resident Live Births Occurring Outside of Michigan by Place of Occurrence, and Live Births Occurring in Michigan to Non-Michigan Residents by Place of Residence, 1979

Canada..........	94	5.2	15	2.5
Other Areas.....	151	8.4	137	23.0

PLACE OF BIRTH

In 1979 99.44 percent of the 143,240 infants born in Michigan were delivered in hospitals. There were 619 infants born at home, and 184 other non-hospital deliveries (Table 1.29). While the percentage of infants not born in hospitals is still very small, the number of home deliveries and other out-of-hospital births has increased in recent years. Between 1973 and 1979 the number of infants born at home increased by 120 percent, while the proportion of all live-born infants who were delivered at home increased from 0.20 percent in 1973 to 0.43 percent in 1979.

ATTENDANT AT BIRTH

Data in Table 1.30 reveal that 99.5 percent of the live births which occurred in Michigan were attended by a physician, either an M.D. or D.O. There were 257 live births attended by the mother's husband, while nurses delivered 137 infants and midwives and nurse-midwives delivered 44 babies. During 1979 there were 66 infants born to unattended women.

Of the 619 infants born in the mother's home 31.0 percent were attended by a physician, while an additional 36.5 percent were attended by the husband.

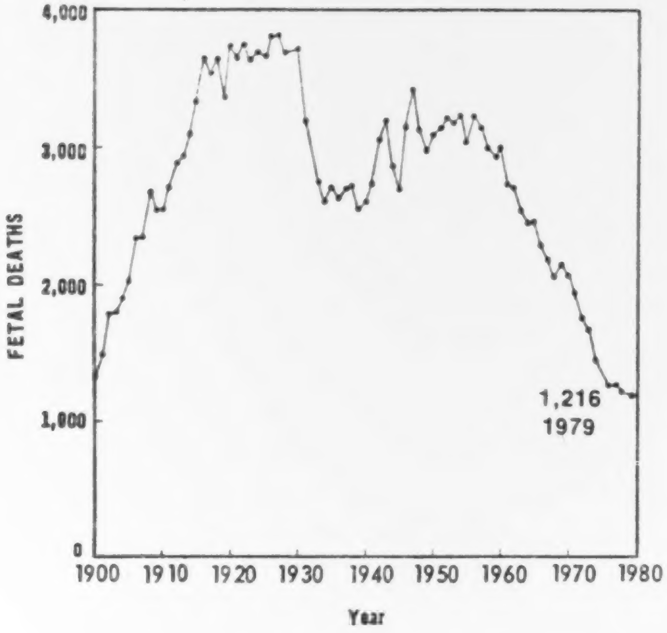
FETAL DEATHS

There were 1,325 fetal deaths reported in 1900 through the death registration system. The number of reported fetal deaths increased from 1900 through 1916. In 1916 there were 3,689 fetal deaths (Figure 1.9). The numbers of such deaths were relatively stable from 1916 through 1930, with the peak year for the period being 1927. This year marked the highest frequency of occurrence in this century with 3,834 fetal deaths. Over the period 1930 through 1939, fetal deaths declined, reaching 2,572. Fetal deaths then increased through 1943, decreased in 1944 and 1945, and increased again to 3,422 in 1947. Fetal deaths numbered between 3,000 and 3,250 in the period 1948 to 1958. In the 1960's and 70's the number of fetal deaths declined sharply. By 1976, the number of fetal deaths fell to 1,271, the lowest number reported in this century. The figure was slightly higher in 1977 (1,288). In 1978 and 1979 new lows of 1,221 and 1,216 were observed, respectively.

Part of the decline in fetal deaths from 1977 to 1978 was due to the introduction of a new reporting form on October 1, 1978. The principal responsibility for reporting a fetal death was shifted from the funeral director to the hospital or other institution where the delivery occurred. Michigan resident fetal deaths numbered 966 in the first nine months of 1977 and 963 in the same period during 1978. There was a significant decline between 1977 and 1978 in the number of fetal deaths reported for the transitional month of October (117 in 1977 and 69 in 1978). In the last two months of 1977 there were 205 fetal deaths reported compared to 189 in the last two months of 1978. This problem of underreporting was addressed, and the fetal death file for 1979 is believed to be complete.

The fetal death ratio for Michigan has declined through most of the twentieth century (Figure 1.10 and Table 4.2). The ratio rose from 30.3 in 1900 to 43.5 in 1905. Through the teens and early twenties, this ratio fluctuated between 38 and 42, never reaching the peak ratio observed in 1905. In 1922, Michigan's fetal death ratio was 42.0. The year 1922 marks a turning point, as fetal death ratios have generally declined since this year. The low ratio of 1900 was first succeeded by a new low

FIGURE 1.9 Fetal Deaths, Michigan Residents, 1900-1979



ratio in 1936 (29.7). Over the next 43 years, new lows have been established repeatedly, as the fetal death ratio continues to decline. The ratio in 1979 was 8.4, the lowest observed in this century.

National fetal death data are presented in Figure 1.10 and Table 1.31. Michigan's fetal death ratios have generally been below national ratios. In fact, the United States ratio has been below that for Michigan in only six of the 56 years for which national data are available. The last time the United States ratio was below the Michigan ratio was in 1947. In 1977, the Michigan ratio was 6.1 percent below the national ratio of 9.9. It should be noted that fetal deaths in Michigan are comprised of stillbirths that have passed through 20 weeks gestation. This definition is different from that of some states. (Since October 1 of 1978 stillbirths of fetuses of less than 20 weeks gestation weighing 400 grams or more are also required to be reported as fetal deaths. The impact of this change in definition on the number of fetal deaths reported has been minimal.

CAUSES OF FETAL DEATH

A classification of fetal deaths by underlying cause of death is contained in Table 1.32. This classification is based on the 9th Revision of the International Classification of Diseases which was introduced in 1979. Since major changes were made between the 8th and 9th Revisions of the ICD in the section used for classifying causes of fetal death, comparisons between cause-specific ratios for 1979 and those for previous years require detailed study. Also, since a relatively large number of deaths are allocated to unspecified causes, caution should be exercised in attempting to draw specific inferences regarding causes of death.

In 1979, 325 of the total 1,216 deaths were assigned to the category of "Other and ill-defined conditions originating in the perinatal period" and of these 325 fetal deaths 267 were in the "unspecified" category. Nearly half (44.7 percent) of the fetal deaths for which a cause was stated were attributed to complications of

1 - Ninth Revision of the International Classification of Diseases.
2 - Ratios per 100,000 resident live births.

placenta, cord, and membranes (ICD 762). This is a group of maternal conditions which includes placenta previa, premature separation of the placenta, placental hemorrhage, and compression of the umbilical cord. Second in frequency was the category maternal complications of pregnancy (ICD 761), which was listed as the cause of 112 fetal deaths. This includes such complications as premature rupture of membranes, multiple pregnancy, and incompetent cervix. Disorders relating to short gestation and unspecified low birthweight were the cause of 88 fetal deaths. Of the 77 deaths caused by congenital anomalies, 26 were attributed to anencephalus or similar anomalies.

AGE OF MOTHER AND RACE OF FETUS

It appears that the younger, the older, and other than white mothers have a greater risk of delivering a stillborn fetus. The rates of fetal loss for mothers under 15 years, 40 years or over, and for the other than white fetus are higher than those for other groups (Table 1.33).

The overall fetai death rate per 1,000 total births (live births plus fetal deaths) was 8.3 in 1979. An association of maternal age with fetal death rates is apparent from Table 1.33. The 25-29 year age group displayed the lowest rate. Progressively older and younger age groups displayed increasingly higher rates. The rate for women 15-19 (9.1) was 28.2 percent higher than the rate for women 25-29 years of age (7.1). The highest rates were experienced by girls under 15 years and by women 40 years or over. The rate for these groups (22.0) was over three times the rate for women in the lowest risk age group. The median age of women whose pregnancy resulted in a fetal death was 24 years, the same as for women having live births.

In 1979 the fetal death rate for white fetuse's was 7.0 while the fetal death rate for other races was 84.3 percent higher at 12.9. Rates for other than white fetuses were higher than for white fetuses in all age intervals with sufficient events to calculate rates. The differentials ranged from 39.5 percent for women aged 15 through 19 to 134.5 percent for women aged 25-29.

INTERPREGNANCY TIME PERIOD FOR FETAL DEATHS

For those women whose pregnancy terminated with a fetal death in 1979, a total of 497 reported the date of the termination of a previous pregnancy. The median interpregnancy time period was 2 years and 5 months, compared to 2 years and 7 months for women having live births in 1979. Table 1.34 presents a comparison of fetal death rates by interpregnancy time span for births in 1979 to women who reported the date of a prior termination. The minimum risk was associated with spacings of between 2 and 3 years (4.2 fetal deaths per 1,000 total births). The risk increased progressively as the length of spacings decreased or increased. The fetal death rate for births with spacings of five or more years was 61.9 percent above the rate of the minimum risk category. The greatest risk of fetal death was associated with spacings of less than one year. For births in this category the fetal death rate (18.8) was four and a half times the rate for the minimum risk category. When comparing interpregnancy time spans for live births and fetal deaths one should be aware that the shorter gestationalperiod associated with fetal deaths results in a correspondingly shorter interpregnancy time span.

Table 1.35 indicates that, as with live births (Table 1.13), the outcome of the immediate prior termination has a strong influence on the interval between pregnancies. For 116 women whose prior termination was a fetal death, the median interpregnancy time span was 1 year and 8 months. For 381 women whose prior termination was a live birth, the median interpregnancy time span was 2 years and 9 months.

As for live births, the median interpregnancy time span for fetal deaths has declined since 1977. In 1977 the median was 2 years and 11 months for fetal deaths. By 1979 the median had declined 17.1 percent, to 2 years and 5 months. For live births the decline was 6.1 percent, from 2 years and 9 months in 1977 to 2 years and 7 months in 1979.

Table 1.34 Fetal Deaths, Live Births, Total Births, and Fetal Death Rates by Interpregnancy Time Span, Michigan Residents Reporting Prior Pregnancy Terminations[1], 1979

2 - Terminations with time spans of zero years (i.e., second or later births in plural deliveries) and terminations with unknown time spans are excluded.

3 - Fetal deaths of any gestational age.

PRENATAL CARE - FETAL DEATHS

Of the 1,216 fetal deaths reported for 1979, 96 or 7.9 percent of the reports indicated that the mother had no prenatal visits. The comparable percent for live births was 0.6. The percent of mothers with fewer than ten prenatal visits was 55.6 for fetal deaths and 28.1 for live births (Table 1.16 and Table 1.36).

The number of prenatal visits varied by race (Table 1.36). Mothers of white fetuses had a mean of 7.7 visits whereas those of other than white fetuses reported a mean of 5.4 visits. Note, however, that the number of prenatal visits was not stated on 16.7 percent of the reports for white fetuses and 21.3 percent of the reports for other than white fetuses.

The fetal death rate varied with the number of prenatal visits (Table 1.37). The rate was 96.7 for mothers with no care, 32.2 for mothers with 1-4 visits, and 11.3 for those with 5-9 visits. The fetal death rate was lowest for mothers with 10-14 visits (2.9), and increased to 3.5 and 4.0 for mothers with 15-19 and 20 or more visits, respectively.

Fetal death rates for white and other than white fetuses exhibited similar patterns of association with the number of prenatal visits (Table 1.37). The overall fetal death rate for other than white fetuses was 84.3 percent higher than for white fetuses. However, when fetal death rates for white and other than white fetuses are compared within prenatal care categories the differentials are reduced. The death rates were similar for white and other than white fetuses born to women who received between 15 and 19 prenatal visits, while the fetal death rate for white fetuses was about one and a half times that for other than white fetuses for fetuses born to women who received from 1 to 4 prenatal visits.

Caution should be exercised in interpreting the above fetal death rates and proportions. Incomplete reporting of the number of visits occurred on 19.9 percent of the fetal death reports compared with 3.5 percent of the live birth records. It should also be kept in mind that fetal deaths are much more likely to occur preterm

1 - Race not stated included in total columns only.

and this affects the possible number of prenatal visits (Table 1.38). In 1979 27.5 percent of the reported fetal deaths occurred before 28 weeks of gestational age, and 52.2 percent occurred before 36 weeks. Incomplete reporting of gestational age occurred on an additional 14.0 percent of the fetal death reports.

The month of pregnancy that prenatal care began was most frequently the second month (Table 1.39). A majority (58.3 percent) of women reported receiving care prior to the fourth month of pregnancy, with 72.1 percent receiving care prior to the sixth month. From 1970 through 1973 there were increases in the percentage of fetal deaths in which the mother received care prior to the fourth and sixth month. These percentages declined between 1973 and 1976, and increased during the past three years (Figure 1.11).

FETAL WEIGHT

Among live births, the percent of infants weighing 2,500 grams or less at birth was 7.0. The comparable percent among fetal deaths was 66.0. The distribution of fetal weight by plurality for fetal deaths is presented in Table 1.40. Note that twin and triplet deliveries are not sets, but are total occurrences and that any given set may have included live births. The percent of single delivery fetal deaths under 2,501 grams was 65.5. The comparable percent for twin deliveries was 75.8.

The fetal weight distribution is strongly associated with gestational age (Table 1.41). The median fetal weight for all fetal deaths was 1,332 grams compared to a median birthweight of 3,374 grams for live births. For deaths of fetuses of 32-35 weeks age, the median was 1,360 grams, while for the normal gestational age range of 36-39 weeks the median weight was only 2,523 grams.

MEDIAN AGE AT DEATH FOR FEMALES	75 years

MORTALITY: AN OVERVIEW 1979

In 1979 there were 73,480 deaths recorded for Michigan residents, 1,293 fewer than in the previous year. The crude death rate per 1,000 population declined by 1.2 percent, from 8.1 in 1978 to 8.0 in 1979. The age-adjusted death rate declined by 3.2 percent for the total population. Declines were recorded in this rate for each sex-race group. Age-adjusted death rates control for differences or variations in the age composition of the population, and are thus better indicators than crude death rates for showing changes in the risk of dying over a period of time or differences between sex-race groups (see Technical Notes for method of calculation).

Between 1900 and 1979 the number of deaths occurring to Michigan residents increased from 32,453 to 73,480. The 31,472 deaths recorded in 1902 was the lowest number of resident deaths in this century, while the greatest number was recorded in 1972 when total resident deaths numbered 79,210. Although the total number of deaths increased between 1900 and 1979, the increase is due to an increasing population. The crude death rate decreased from 13.4 (per 1,000 population) in 1900 to 8.0 in 1979. The 1979 rate is the lowest crude death rate ever recorded for Michigan. The highest death rate (15.6) was observed in 1918 (Figure 2.1).

A comparison of deaths and crude death rates for Michigan and the United States for the period 1970-1979 is presented in Table 2.1. As Michigan's population is somewhat "younger" than that of the nation, the Michigan rate has consistently been below the United States rate. Both Michigan and national rates were relatively stable between 1970 and 1973, declined in 1974 and 1975, and have dropped but slightly since 1975. Between 1970 and 1979 the number of Michigan resident deaths declined by 3.7 percent, and the crude death rate declined by 7.0 percent. The decline in the age-adjusted death rate was a more dramatic 19.6 percent. Over this period the age-adjusted death rate for the nation declined by a similar amount, 17.8 percent. In 1970 the age-adjusted death rates of Michigan and the United States were very similar (Table 2.6). Between 1971 and 1973 Michigan's rates were slightly higher, and since 1974 Michigan's rates have been below those of the nation. In the past six years Michigan's age-adjusted death rate has ranged between 1.3 and 2.3 percent below the comparable national figure.

The numbers of deaths by marital status and age for men and women are displayed in Table 2.2. The majority of men were married at the time of death while the majority of women were widows. Men were twice as likely as women to be married at the time of death (59.8 percent compared to 29.7 percent). Conversely, women were over three times as likely to be widows at the time of death as men were to be widowers (53.9 percent compared to 17.0 percent). Among males, 15.2 percent had never been married, while the corresponding figure for females was 10.5 percent. Men were also more likely to be divorced (7.6 percent compared to 5.7 percent).

Table 2.3 presents data on the number of deaths by race for the period 1970-1979. The number of deaths of white persons declined by 4.9 percent over the decade while deaths of black persons increased by 5.2 percent. Reported deaths of American Indians and persons of other races remained fairly constant. It should be noted that reported race data are derived from the death certificates filed by funeral directors. Data from sources where race is self-enumerated, when matched with death data, indicate larger numbers of American Indians and persons of other races than reported as members of those groups on the death certificate.[1] In 1979 deaths of white persons numbered 63,955 and accounted for 87.0 percent of all deaths, while deaths of black persons constituted 12.5 percent of the state total.

Michigan resident deaths in 1979 are tabulated by age, race, and sex in Table 2.4. Of the 73,480 Michigan resident deaths that occurred in 1979, 40,652 (55.3 percent) occurred to males and 32,820 occurred to females (8 records had sex not stated). The median age at death for males was 68 years, compared to a significantly higher figure of 75 years for females. The median age at death was 72 years for whites, compared to 62 years for persons of other races.

[1] Deaths of eight white persons with sex not stated are included only in the total columns.

In 1979, 26,002 or 35.4 percent of all deaths occurred to persons under the age of 65. The proportion dying under age 65 was higher for males than females and higher for other than white persons than white persons. For white persons 37.9 percent of males and 25.7 percent of females died before age 65. For other than white persons 60.1 percent of males and 49.0 percent of females died before age 65.

Unadjusted, age-specific, and age-adjusted death rates by race and sex are presented in Table 2.5. The rate for males of 897.8 was 28.0 percent above that for females while the age-adjusted rate for males was 72.9 percent higher. The population subgroup with the lowest death rate was other than white females (608.4) and the highest rate was experienced by white males (900.0). Age-adjusting the data results in a quite different relationship, however, with the age-adjusted rate being lowest for white females and highest for other than white males.

The age-specific death rates for all males and all females displayed in Figure 2.2 indicate a similar pattern of rising and falling rates across the age intervals presented. The rates for both sexes declined from birth to a low for ages 5-9 years. The rates for 15-19 year olds were much higher than for 10-14 year olds in both sexes. The rates rose, declined and then rose persistently through the terminal age group (85 and over). The rates for males were consistently above those for females with the greatest relative differentials occurring in the ages 15-29 years, where the rates for males were between two and a half and three times those for females.

A comparison of 1979 age-specific death rates for males by race is graphically presented in Figure 2.3. Note that the rate for white males increased between ages 10 and 29 and then declined for ages 30-34. The rate for other than white males rose more rapidly between the ages of 20 and 29 years. The only ages prior to age 65 in which the rates for white males were not below those for other than white males were ages 10-19. Beyond age 64 the rates for whites were higher, with the exception of the age group 75-79 years. Between the ages of 25 and 49, rates for other than white males were about 2 to 4 times the rates for white males. The overall death rate

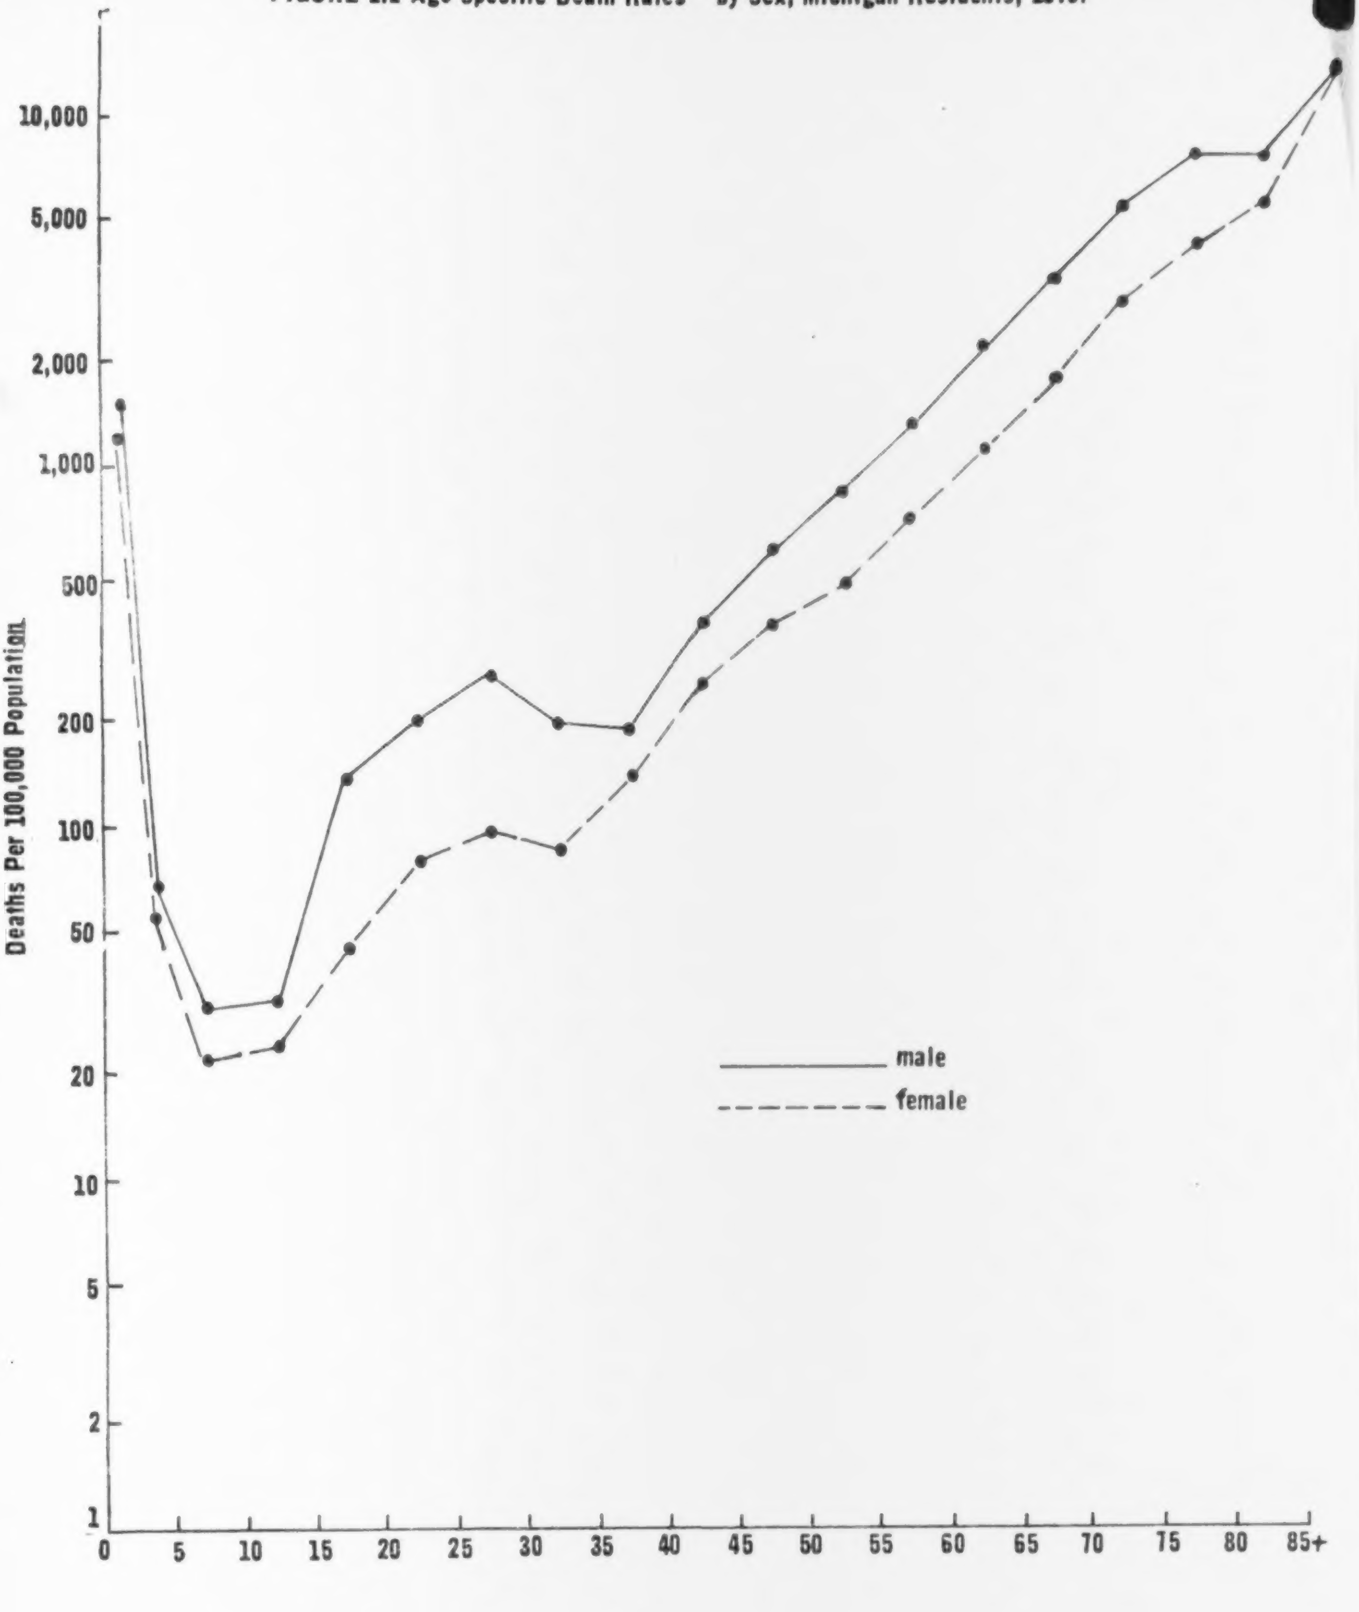
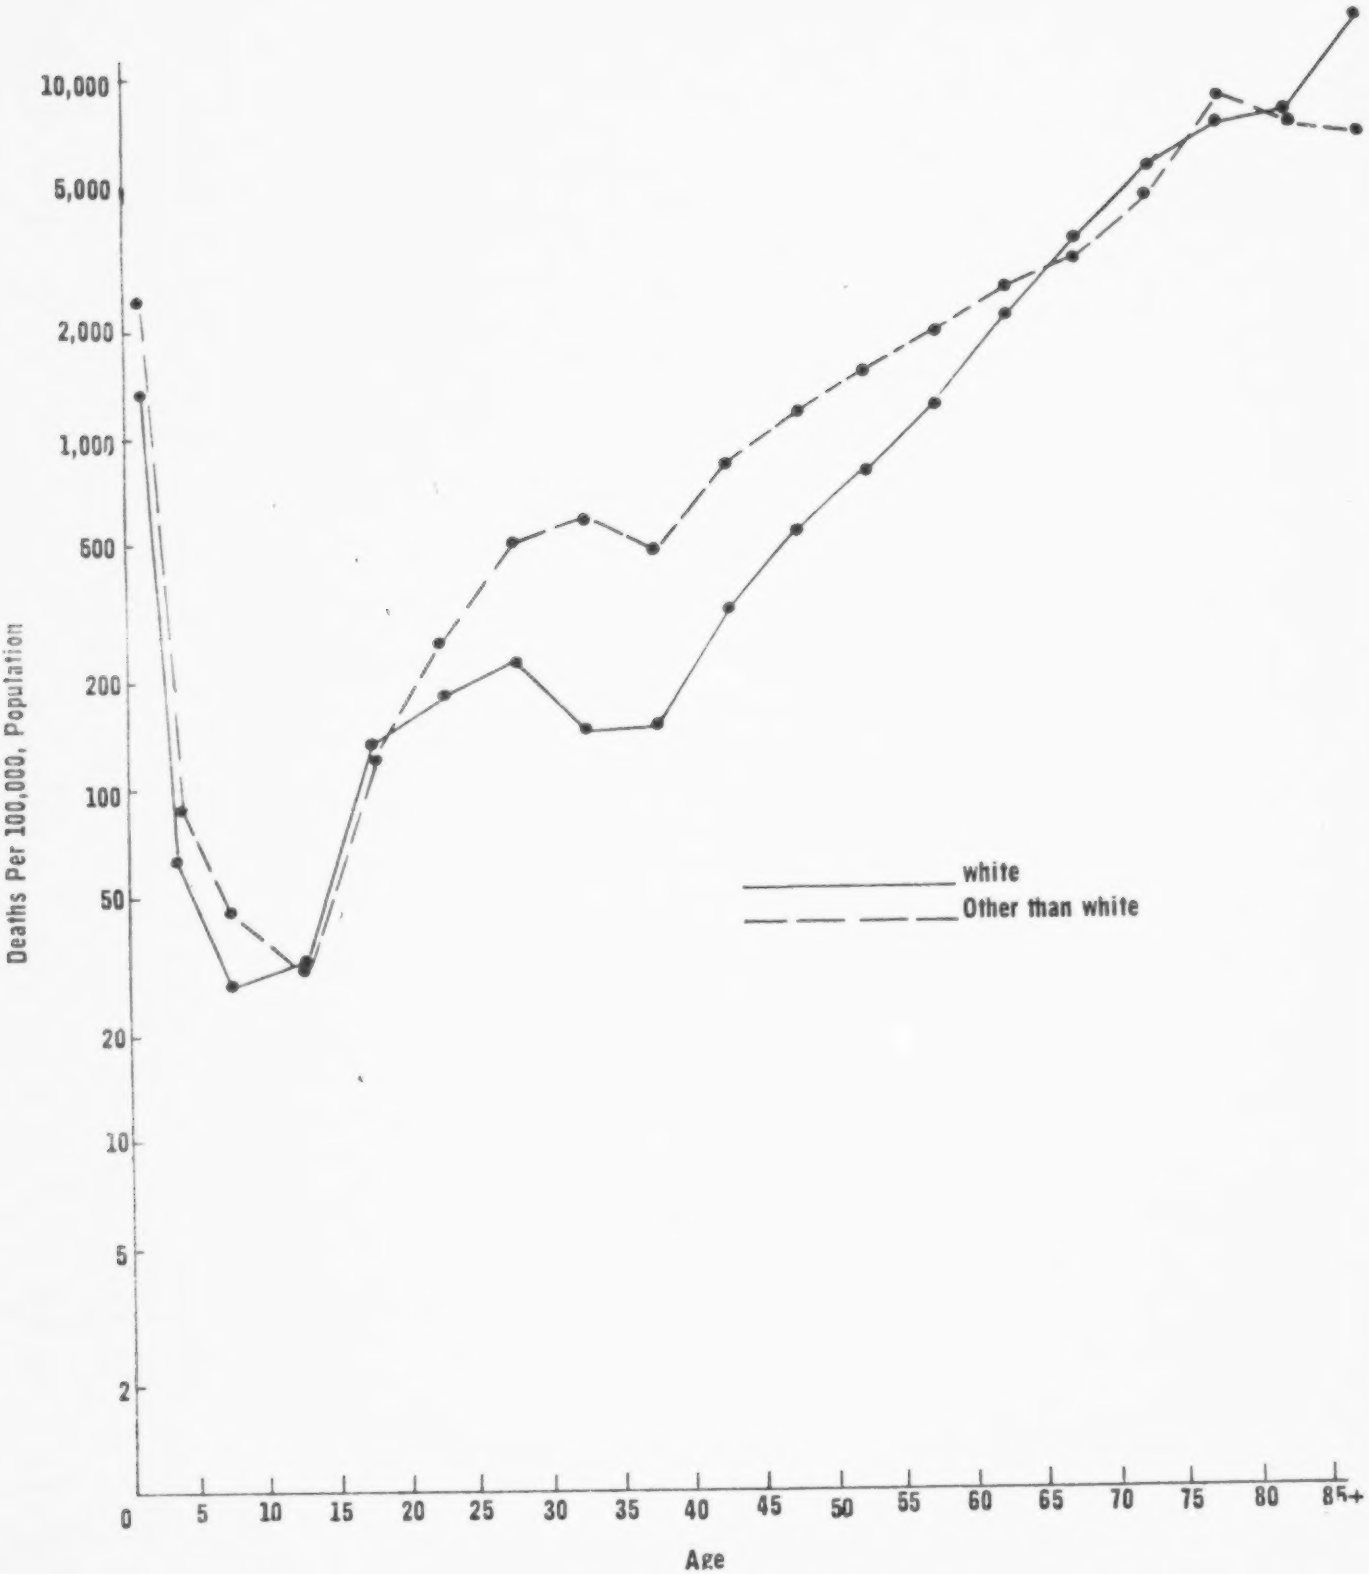
[1] Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see technical notes.

FIGURE 2.2 Age-Specific Death Rates [1] by Sex, Michigan Residents, 1979.



[1] - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

FIGURE 2.3 Age-Specific Death Rates,[1] by Race, Michigan Resident Males, 1979



1 - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences

of 883.8 per 100,000 for other than white males was slightly below the rate for white males (900.0). This is a reflection of the younger age distribution of the other than white male population. The age-adjusted death rate for other than white males was 31.1 percent higher than that for white males.

Rates for other than white females were higher than those for white females except in the age group 15-19 and beyond age 79 (Figure 2.4). Between the ages of 25 and 59, the rate for other than white females ranged between 1.8 and 3.6 times the rate for white females. The death rate for all ages was 716.7 for white females and 608.4 for other than white females, reflecting the greater concentration of the white female population in the older age intervals with relatively high death rates. After adjusting for differences in the age distributions of the populations, the rate for other than white females was 40.7 percent higher than that for their white counterparts.

Age-adjusted death rates for other than white persons have been considerably higher than comparable rates for white persons throughout the 1970's (Table 2.6). Age-adjusted rates for other than white males ranged between 30 and 41 percent higher than comparable rates for white males in Michigan. For females this differential is even greater with the rate for other than white women exceeding that for white women by 37 to 51 percent. There has been, however, a small reduction in the size of the differential in the past few years.

Declines have occurred in the 1970's both in Michigan and the United States in age-adjusted death rates in each race-sex subgroup. Michigan's age-adjusted rate for the population as a whole declined by 19.6 percent between 1970 and 1979 while the estimated decline for the United States was 17.8 percent. Relative declines in both Michigan and the United States were slightly greater for the other than white population. Although age-adjusted rates for white females in Michigan are comparable to rates for white females observed nationally, the rates for white males and for other than white males and females in Michigan have generally been somewhat below those for the nation in the past several years.

1 - Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see Technical Notes.

LEADING CAUSES OF DEATH

Deaths assigned to the 10 leading causes accounted for 85.9 percent of all deaths in 1979. Causes of death in 1979 were classified according to the Ninth Revision International Classification of Diseases (ICD-9) published by the World Health Organization. Cause-of-death ranking used in Michigan is identical to that used by the National Center for Health Statistics (NCHS). It is based on the List of 72 Selected Causes of Death, which NCHS constructed by combining titles in the List of 282 Selected Causes of Death. This latter list, which is also used in this publication, was in turn constructed by aggregating the detailed titles of the Ninth Revision.

During the years 1968-1978 the Eighth Revision International Classification of Diseases, Adapted for Use in the United States (ICDA-8) was used to classify causes of death. The introduction of the Ninth Revision resulted in some major changes between 1978 and 1979 in the classification of causes of death. Since the new categories under ICD-9 differ in content from those under ICDA-8, comparability ratios to measure the similarity were developed by NCHS. Table 2.7 presents the numbers of deaths and death rates for the 10 leading causes of death in 1978 and 1979, as well as the comparability ratios between the Ninth Revision categories and the most nearly comparable Eight Revision categories. Comparability ratios were developed by coding a sample of 1976 deaths using the Ninth Revision, and dividing the estimated number of deaths assigned to a particular cause under the Ninth Revision by the actual number of deaths coded to the most nearly comparable category in accordance with the Eighth Revision. Thus, multiplying the comparability ratio for a cause of death by the death rate for that cause in 1978 yields an adjusted death rate which is an estimate of the death rate that would have resulted from coding 1978 deaths by the Ninth Revision. It should be noted that a comparability ratio of 1.00 does not necessarily indicate that the cause was unaffected by changes in classification and coding procedures because the changes may compensate for each other.

Several of the titles of the leading causes of death in 1979 were altered. The

TABLE 2.7 - Leading Causes of Death and Comparability Ratios, Michigan Residents, 1978 and 1979

Cause of Death (ICD-9)	Estimated Comparability Ratio[1]	1978		1979		Adjusted 1978 Rate

Population Estimate, July 1		9,189,000		9,207,000		

[1] Source: Monthly Vital Statistics Report, Vol. 28, Number 11, Feb. 29, 1980, published by NCHS.

[2] The most nearly comparable group of diseases under the 8th Revision is composed of bronchitis, emphysema, asthma, and chronic obstructive lung disease without mention of asthma, bronchitis or emphysema. No single comparability ratio was developed for the 9th Revision category and the most nearly comparable 8th Revision categories. However, for the combined categories of bronchitis, emphysema, and asthma the provisional comparability ratio is 1.0002, and that for the remaining titles (chronic obstructive lung disease without mention of asthma, bronchitis, or emphysema under the 8th Revision and other chronic obstructive pulmonary diseases and allied conditions under the 9th Revision) is 1.0054. Thus, the comparability between the composite categories is quite good. The composite category was not used for ranking causes of death under the 8th Revision and thus appears for the first time among the 10 leading causes of death.

[3] This category was termed cirrhosis of the liver under the 8th Revision.

[4] This category was termed arteriosclerosis under the 8th Revision.

Eighth Revision categories of accidents, influenza and pneumonia, arteriosclerosis, and cirrhosis of the liver are termed accidents and adverse effects, pneumonia and influenza, atherosclerosis, and chronic liver disease and cirrhosis, respectively, under the Ninth Revision. The ranking of the four leading causes of death did not change between 1978 and 1979. The fifth leading cause of death in 1979, chronic obstructive pulmonary diseases and allied conditions, is a new category comparable to the Eighth Revision categories of bronchitis, emphysema, asthma, and chronic obstructive lung disease without mention of asthma, bronchitis, or emphysema. This latter category was used increasingly by physicians during the 1970's in preference to the more specific categories. During the years in which the Eighth Revision was used, bronchitis, emphysema, and asthma were grouped together for purposes of ranking, and chronic obstructive lung disease without mention of asthma, bronchitis, or emphysema was not used in ranking. The order of the causes ranked sixth to tenth in 1979 is identical to that of the causes ranked fifth to ninth in 1978. The tenth leading cause of death in 1978, homicide, is no longer ranked among the top ten. The number of homicides in 1979 was 882. The percentage of the total deaths resulting from each of the ten principal causes is illustrated in Figure 2.5 for 1979.

Crude death rates in Michigan were lower in 1979 than the comparable adjusted 1978 rates for seven of the ten leading causes. Although no adjusted rate for 1978 for chronic obstructive pulmonary diseases and allied conditions is available, the number of deaths in 1979 (1,934) is lower than the number (1,974) assigned in 1978 to the most nearly comparable categories. In 1979 only the rate for malignant neoplasms increased, while the suicide rate was unchanged.

The order of the 10 leading causes for the United States in 1979 was identical to that for Michigan. Certain differences between the United States figures and those of Michigan should be noted. The overall Michigan death rate was significantly lower than the national rate. The rates for diabetes mellitus and chronic liver disease and cirrhosis, however, were higher than comparative national rates (Table 2.8).

Table 4.8 shows the numbers of deaths and death rates for several major causes

	Total	73,480	1,906,000	798.1	866.2

[1] United States figures are provisional.

for each year during this century. There has been no change in the ranking of the four leading causes over the 30 years since 1950. From 1950 through 1978 the ranking of 5th and 6th have been held by diabetes mellitus and pneumonia and influenza, with pneumonia and influenza ranking 5th in 19 of the 29 years. For the past five years pneumonia and influenza has ranked before diabetes. The 8th leading cause of death in 1979, chronic liver disease and cirrhosis (formerly titled cirrhosis of the liver) was not among the ten leading causes of death in 1950. This cause ranked 10th in 1954 and has been among the ten most frequent causes consistently since 1960. It was the 7th leading cause each year from 1969 through 1978. Atherosclerosis, previously termed arteriosclerosis, has consistently been among the ten leading causes of death, ranking 7th in 1950 and 9th in 1979. Suicide first ranked in the top ten in 1964 when it was the 10th leading cause. During the past six years atherosclerosis and suicide have alternately ranked 8th, 9th, and 10th. In 1979, seven of the ten leading causes of death were chronic conditions, one was an acute disease category, and two were external non-disease groupings.

While the most frequent causes of death among all Michigan residents have changed little in recent years, this does not imply similarity in the leading causes of death among residents at different ages, of different sexes or different races. Table 2.9 presents the five most frequent causes of death by age, sex and race. Careful examination of this table will disclose that major differences in the leading causes of death are associated with these three characteristics. No single cause of death is among the most frequent causes in all categories. Heart disease, malignant neoplasms and accidents have the most widespread significance, being present respectively in 26, 25, and 27 of the 32 age-sex-race groupings. The variation in leading causes of death by age is most evident among deaths to infants under one year. This category has little similarity to any other age group. External causes of death, including accidents, suicide and homicide, are predominant killers among persons 1 through 34 years of age. Among persons 35 years and over, chronic conditions are responsible for the largest percentage of deaths.

DISEASES OF THE HEART

The leading cause of death, heart disease , caused 29,296 Michigan resident deaths in 1979. This is more than the number of deaths from the next five largest causes combined. The number of deaths from heart disease in 1979 was 110 fewer than in 1978. The crude rate of 318.2 deaths per 100,000 population from this cause is slightly lower than the rate of 320.0 in 1978. This apparent decline is somewhat less than the decline that would have been observed if causes of death had been assigned based on the same Revision of the ICD in both 1978 and 1979. Based on an adjusted rate of 324.0 (see Table 2.7) for 1978, the decline in the crude death rate was 1.8 percent between 1978 and 1979.

The median age of persons who died from heart disease was 75 years, compared to a median of 71 years for deaths from all causes. Of the 29296 deaths due to diseases of the heart, 55.0 percent were to males. The median age at death for males was 71 years compared to 79 years for females. The median age of 72 years for white males exceeded that for other than white males by 6 years. The median age at death for white females was 80 years, 8 years above that for other than white females (Table 2.10).

Table 2.11 presents death rates for diseases of the heart by age, race and sex. Note that the death rate associated with this cause rises markedly with advancing age. Heart disease was the underlying cause of 42 deaths of persons below 5 years of age or about 1.9 percent of all deaths in this age group. In contrast, 50.7 percent of all deaths in the age group 85 and over were attributed to this cause in 1979. The heart disease death rate was 6,808.1 in the 85 and over age group.

Examination of Table 2.11 reveals that the heart disease death rate for males was substantially higher than that for females in 1979 (355.6 as compared to 281.9 per 100,000 population). The relationship between rates for males and females is graphically displayed in Figure 2.6. Age-specific heart disease death rates for males and females were similar below the age of 20. Rates for males were substantially above those of females between ages 20 and 84. The greatest differentials occurred between the ages of 35 and 64 with rates for males ranging between 2.5 and 3.4 times the corresponding rates for females. The gap between rates for males and females became progressively smaller between ages 65 and 84, and beyond age 85 the heart disease death rate for females exceeded that for males. The age-adjusted death rate for males was 1.9 times that for females.

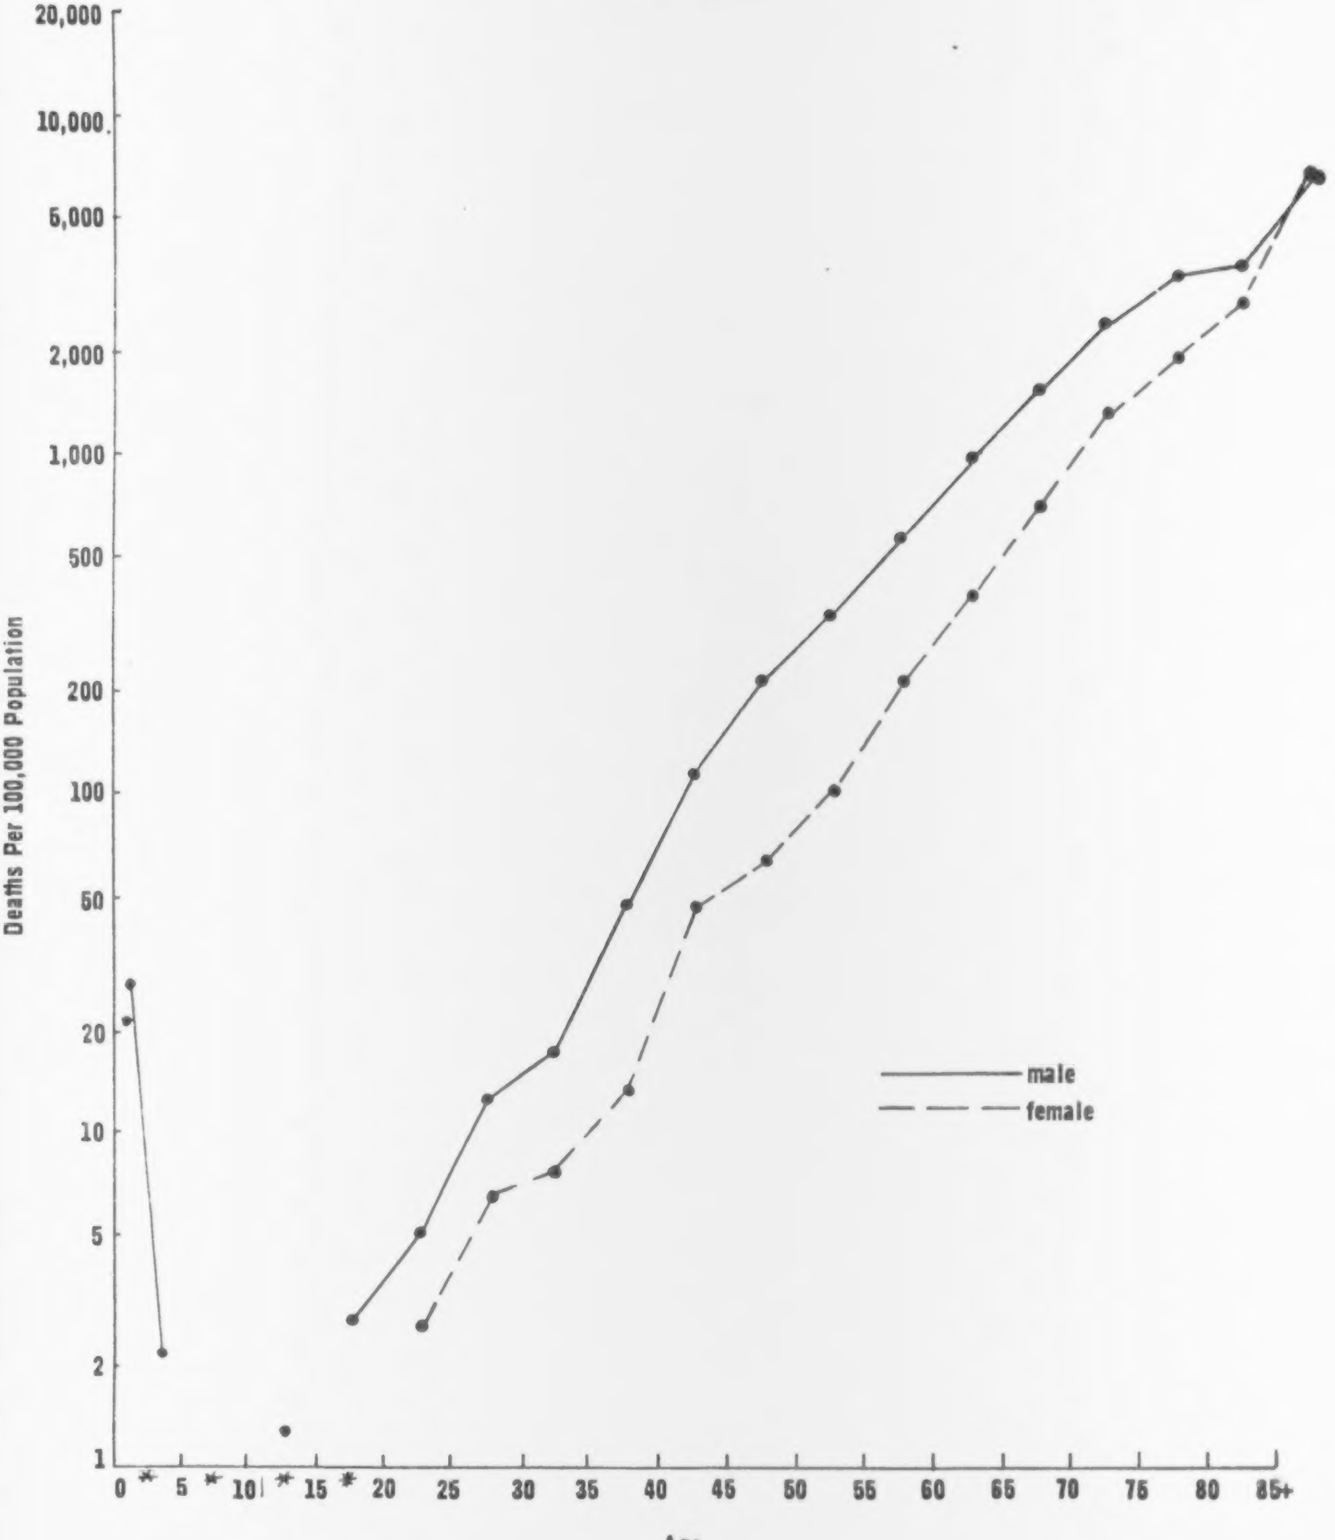
FIGURE 2.6 Age-Specific Heart Disease Death Rates[1] by Sex, Michigan Residents, 1979



---

[1] - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

A comparison of 1979 heart disease death rates for males by race is graphically presented in Figure 2.7. Rates for other than white males were higher than those for white males between ages 20 and 59 and lower than rates for white males in all age intervals beyond age 59 except the 75-79 age group. The rate for white males across all ages was 370.0 compared to 264.2 for other than white males. This differential stems largely from the fact that a greater proportion of the white male population was in the older age groups where heart disease death rates were particularly high. The age-adjusted heart disease death rate for white males was 279.1 in 1979, 0.7 percent above the rate of 277.2 for other than white males.

Heart disease death rates for white and other than white females are displayed in Figure 2.8. Rates for other than white females were greater than those for white females between ages 25 and 79, beyond which age the rates for white females exceeded those for other than white females. Although the rate for white females for all ages (294.5) was substantially above the comparable rate for other than white females (204.8), this relationship is reversed when the differing age distributions of the two populations are considered. The age-adjusted rate for other than white females was 182.8 while that for white females was 139.0.

In 1900 the crude heart disease death rate in Michigan was 117.1, the lowest rate of this century. Heart disease death rates rose through the time period 1900-1950 and have remained relatively stable over the last twenty-nine years. The highest observed rate during the century was 343.1 in 1965. The annual rate declined in five of the past seven years. The rate of 318.2 for 1979 was 7.3 percent below the peak rate observed in 1965. The rate for Michigan was consistently close to the national rate until 1946. Since that time the crude rate for Michigan has been well below that of the nation. In 1979 the rate for the nation was an estimated 331.3, 4.1 percent above the rate of death due to heart disease for Michigan (Figure 2.9).

Age-adjusted death rates for diseases of the heart in the 1970's are presented in Table 2.12. These data indicate a downward trend in heart disease death rates for the population as a whole and for each race-sex subgroup individually. Between 1970 and

FIGURE 2.7 Age-Specific Heart Disease Death Rates[1] by Race, Michigan Resident Males, 1979

---

[1] - Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see Technical Notes.

1972 the rate for Michigan increased but slightly. Since 1972 the rate has declined each year. The age-adjusted death rate for the nation has declined each year since 1970. Age-adjusted rates have declined by about 20 percent both for Michigan and the nation between 1970 and 1979. The age-adjusted rates for Michigan have been slightly above those for the nation in 8 of the 10 years.

Age-adjusted rates for other than white females have been well above those for white females through the 1970's in both Michigan and the United States. Age-adjusted rates for other than white males have tended to be slightly below those for white males in Michigan and slightly above those for white males nationally.

The most prevalent type of heart disease death is acute myocardial infarction (12,698 deaths in 1979) commonly referred to as a "coronary" (Table 2.13). Almost as frequent is old myocardial infarction and other forms of chronic ischemic heart disease. In 1979 there were 9,187 deaths attributed to this cause. Together, these causes accounted for 75 percent of all Michigan resident deaths from heart disease . Of the remaining 7,411 heart disease deaths, 72 percent were attributed to all other and ill-defined forms of heart disease (4,274 deaths) and heart failure (1,060 deaths).

The probability of eventually dying from heart disease, based on Michigan resident death data from 1977, 1978 and 1979 and population estimates for 1978, is 0.418 for males and 0.439 for females at birth. The chance associated with dying from heart disease increases steadily for both sexes with advancing age as certain competing causes of death become less likely. By age 85, the observed probability is 0.487 for males and 0.525 for females. At all ages the probability of death eventually being caused by heart disease is greater for females. These differentials by sex are smallest between ages 25 and 50. The higher probability for females reflects smaller chances of death due to some cause other than heart disease (Figure 2.10).

An apparent inconsistency can be noted by review of Figure 2.6 and Figure 2.10. The heart disease mortality rate for males is higher than that for females over nearly all ages, yet the chance of eventual death due to heart disease is slightly greater for females at all ages. This paradox is explained by a comparison of these two measures. The

[1] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

cause-specific mortality rate measures the proportion of a population that died from the particular cause over a certain period of time. The probability estimate takes into account the present age-and cause-specific mortality rates and the life expectancy of the population. A greater proportion of all females now alive are expected to live into the older age intervals where they will be subject to the high heart disease mortality rates characteristic of those age groups. The effect of the longer female life span outweighs the effect of the higher mortality rate for males from heart disease.

CANCER

Of 73,480 Michigan resident deaths in 1979, 15,409 were attributed to cancer. Although not the leading cause of death in Michigan or the United States, cancer affects all the human body's major systems and persons of all ages. The frequency of death due to cancer was about one-half that for heart disease across all ages, but the number of cancer deaths below age 60 was about the same as the number of deaths due to heart disease below age 60. The median age at death for cancer was 68, well below the median age of 75 for heart disease deaths (Table 2.14).

Of the 15,409 cancer deaths in 1979 occurring to Michigan residents, 56.7 percent were to males. The median age at death was 68 years for white males and for white females. The median age at death for other than white persons who died of cancer was somewhat lower, 65 for males and 63 for females.

Cancer death rates by age, race and sex are presented in Table 2.15. The cancer death rate across all ages in 1979 was higher for males (188.5) than for females (146.9). The cancer death rates displayed in Figure 2.11 show a strong increase in mortality with advancing age. Age-specific rates for males were higher than those for females in fourteen of the nineteen age groups. Mortality rates were similar for the sexes below age 15. Rates for males were higher between ages 15 and 34. Only in the age groups from 35 through 49 were rates for females appreciably higher than for males. In the first of these age groups (35-39), the rate of cancer mortality for females was double that for males. The relative difference in rates for males and females ages 40-44 was 29 percent and for the 45-49 age group 17 percent. After age 50 the rates for males were greater than those for females. Between ages 50 and 79 the relative differential increased steadily, from 18 percent in the 50-54 year age group to 109 percent in the age group 75-79 years. The age-adjusted cancer rate for males was 46 percent above that for females.

Cancer death rates for white and other than white males recorded in Table 2.15 are graphically displayed in Figure 2.12. Rates for white and other than white males were

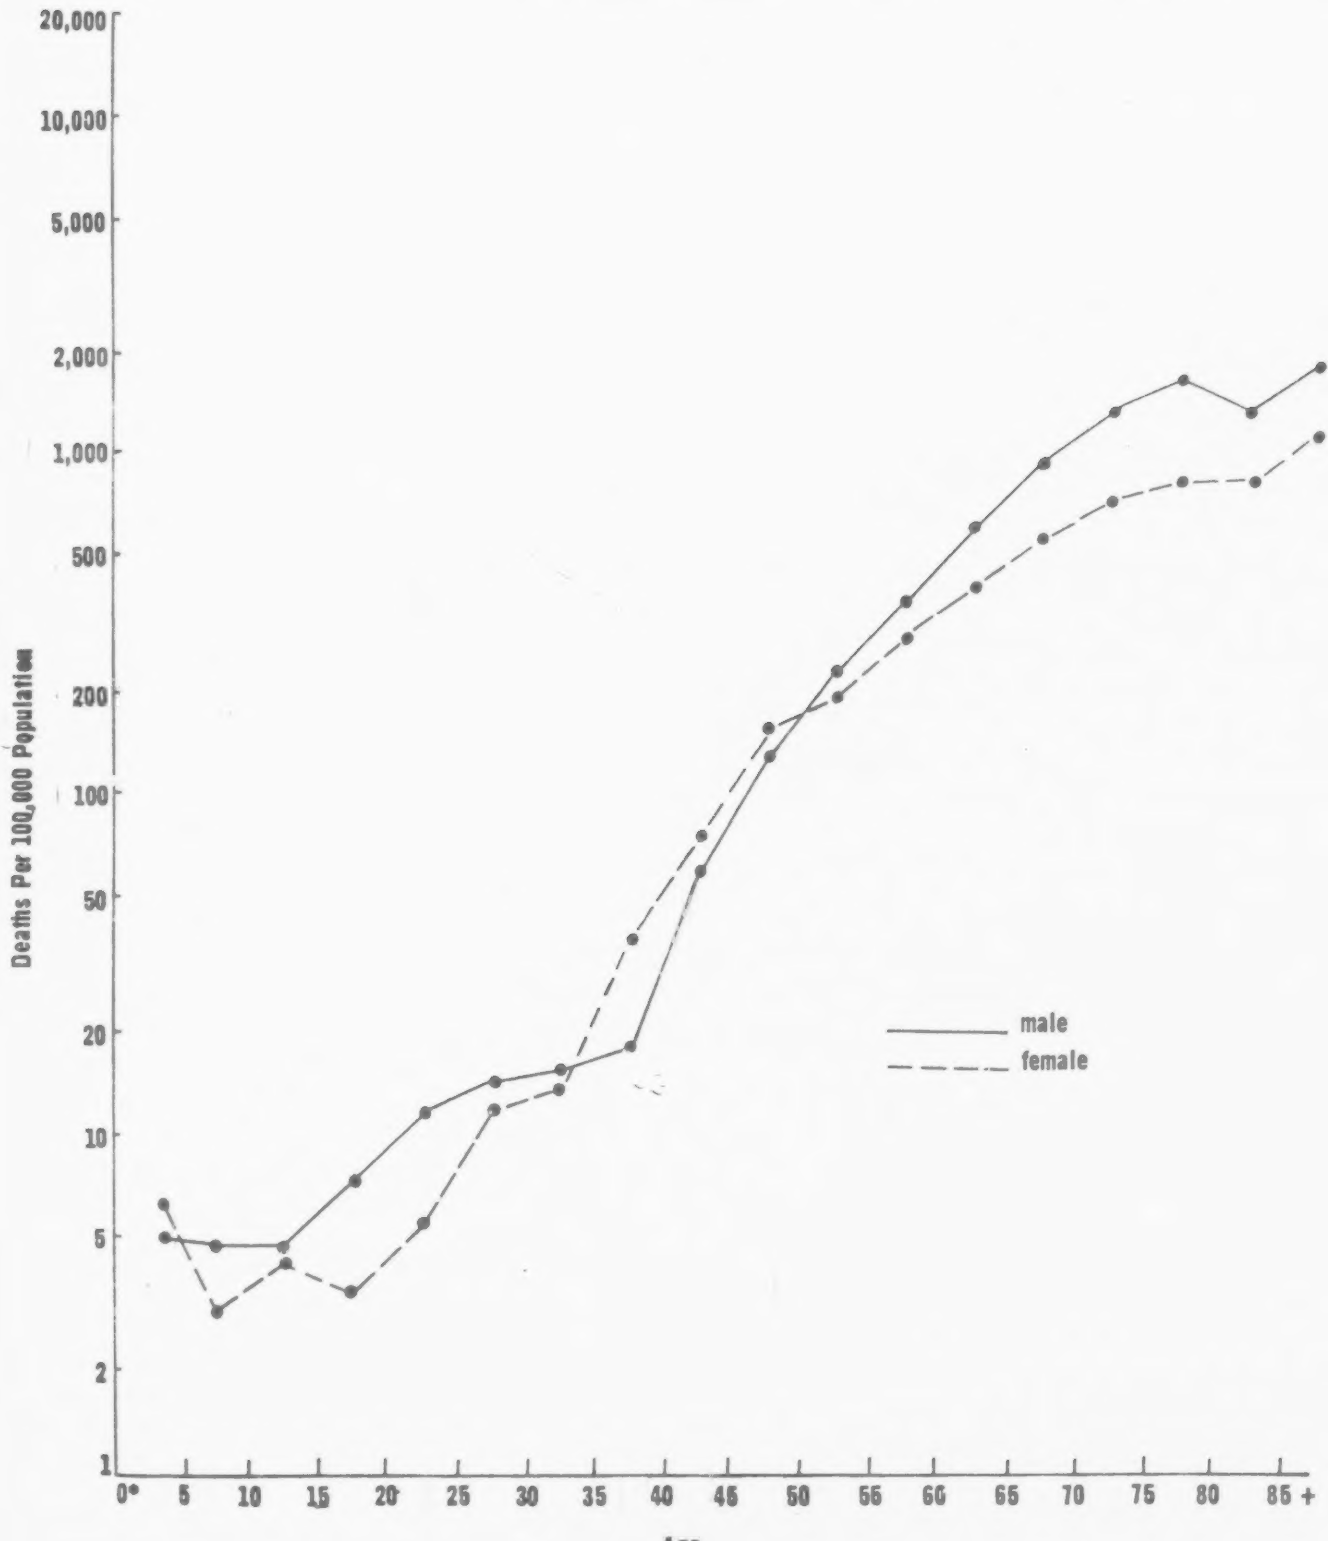
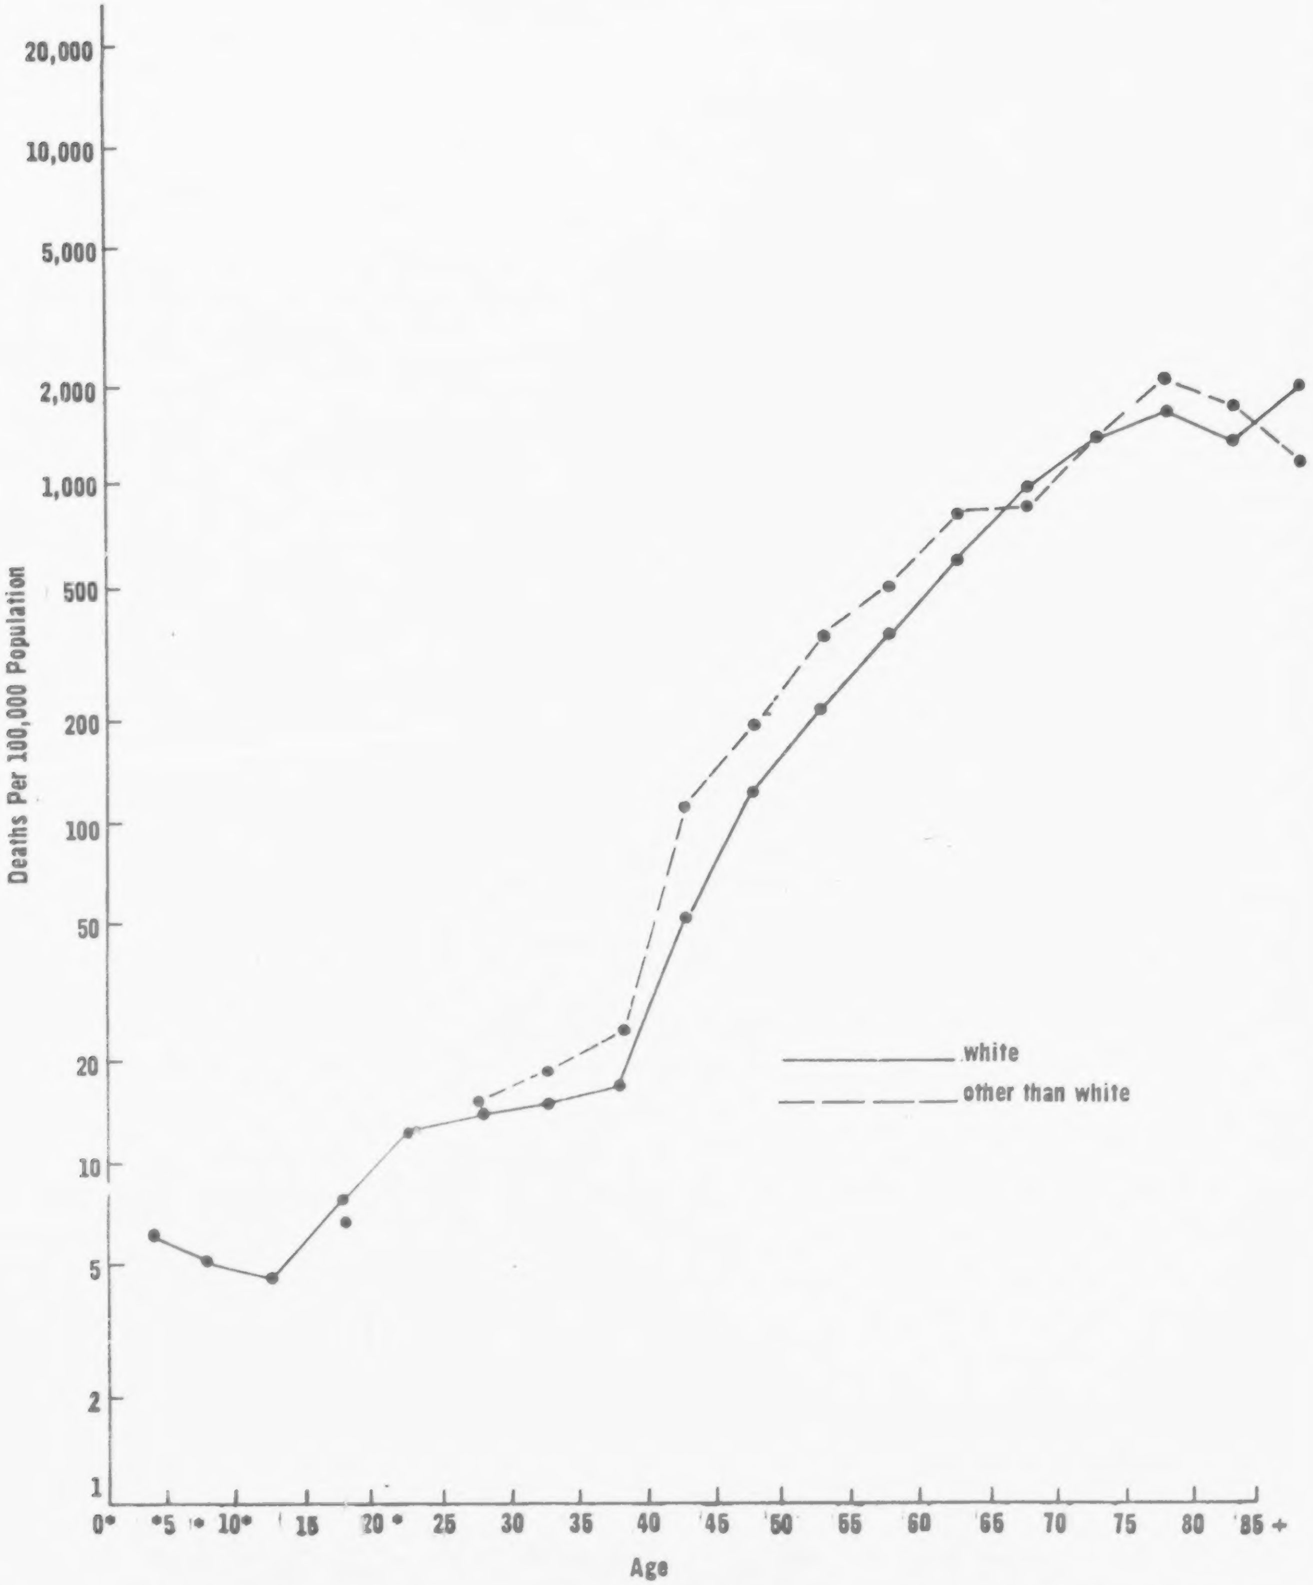
[1] Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see technical notes.

FIGURE 2.11 - Age-Specific Cancer Death Rates [1] by Sex, Michigan Residents, 1979



1 - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

FIGURE 2.12 Age-Specific Cancer Death Rates [1] by Race, Michigan Resident Males, 1979



---

1 - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

quite similar below age 35. Between ages 35 and 64 rates for other than white males were 40 to 100 percent higher than comparable rates for white males. Rates for white males were higher at ages 65-74 and 85 and over. Although the crude death rate for other than white males was slightly below the comparable rate for white males, the age-adjusted rate for other than white males was 21 percent higher than the age-adjusted rate for white males.

Cancer death rates were also similar for white and other than white females below age 35 (Figure 2.13). Rates for other than white females rose above the rates for white females between ages 35 and 59. Rates for other than white females were also higher between ages 70 and 84. The crude rate for white females was one-quarter higher than the comparable rate for other than white females. The age-adjusted rate for other than white females, however, was 15 percent greater than that for white females.

Cancer death rates have risen steadily since 1900 (Figure 2.14). The rate increased for the fifth consecutive year in 1979 to 167.4, the highest observed in this century. The 1979 rate surpassed the previous high rate of 165.9 in 1978. The lowest observed rate for Michigan was 59.3 in 1902. Michigan's cancer death rate was below the national rate from 1900 through 1915. During the period 1916 through 1946 Michigan was generally at the national rate. Since 1947, the state rate has been consistently below the national cancer death rate. Over the last dozen or so years, the rate for the nation rose faster than did the rate observed in Michigan. The national cancer death rate in 1979 was an estimated 183.5. This is 9.6 percent above the state rate.

Age-adjusted cancer death rates for the 1970's presented in Table 2.16 show a much closer relationship between Michigan and United States mortality patterns than that indicated by crude mortality rates. Michigan's 1970 age-adjusted rate for the total population was 3.2 percent higher than the comparable U.S. rate. Since 1970, Michigan's age-adjusted cancer death rate has tended to decline while the U.S. rate increased moderately. As a result, Michigan's age-adjusted cancer death rate has been below the comparable national rate since 1974. Michigan's 1979 age-adjusted cancer death rate of 129.6 was 2.8 percent below the provisional figure for the United States.

	1979	133.4 Pr.	---	---	---	---	---	---	---	---

1 - Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see Technical Notes.

Table 2.16 also allows a comparison of age-adjusted cancer death rates for white males, white females, other than white males and other than white females. The rates for the other than white groups were consistently higher than those for their white counterparts. Rates for white males and other than white males have increased nationally while the rates in Michigan for these groups have exhibited a slight downward tendency. Age-adjusted rates for white and other than white females were essentially stable both in Michigan and the nation.

The numbersof deaths from cancer for 50 different sites are presented in Table 2.17. Malignant neoplasms of the trachea, bronchus, and lung were the underlying cause of 3,744 deaths, 24.3 percent of all cancer deaths. The second most frequent category of cancer mortality was cancer of other and unspecified parts of the colon (1,332). The total number of deaths attributed to colon cancer was 1,597. Breast cancer caused the death of 1,305 females and was the third leading cause of cancer mortality. Malignant neoplasms of the prostate and the pancreas caused 840 and 799 deaths respectively. There were 30 categories which had at least 100 deaths in 1979.

Based upon 1977 through 1979 death data, the probability of death due to cancer is 0.203 for males and 0.176 for females at birth (Figure 2.15). The probability of eventually dying from cancer is greater for males than for females at all ages. The probability for males rises slowly to a peak of 0.215 by age 45 then drops more rapidly to 0.127 at age 85. Probabilities for females display little change from birth to age 45, then diminish to 0.081 by age 85. This decreasing probability beyond age 45, noting the high cancer mortality rates of older age (Figure 2.11), indicates that age-specific death rates due to competing causes of death increase relatively faster with advancing age.

TABLE 2.17 - Deaths Due to Malignant Neoplasms by Site Affected, Michigan Residents, 1979

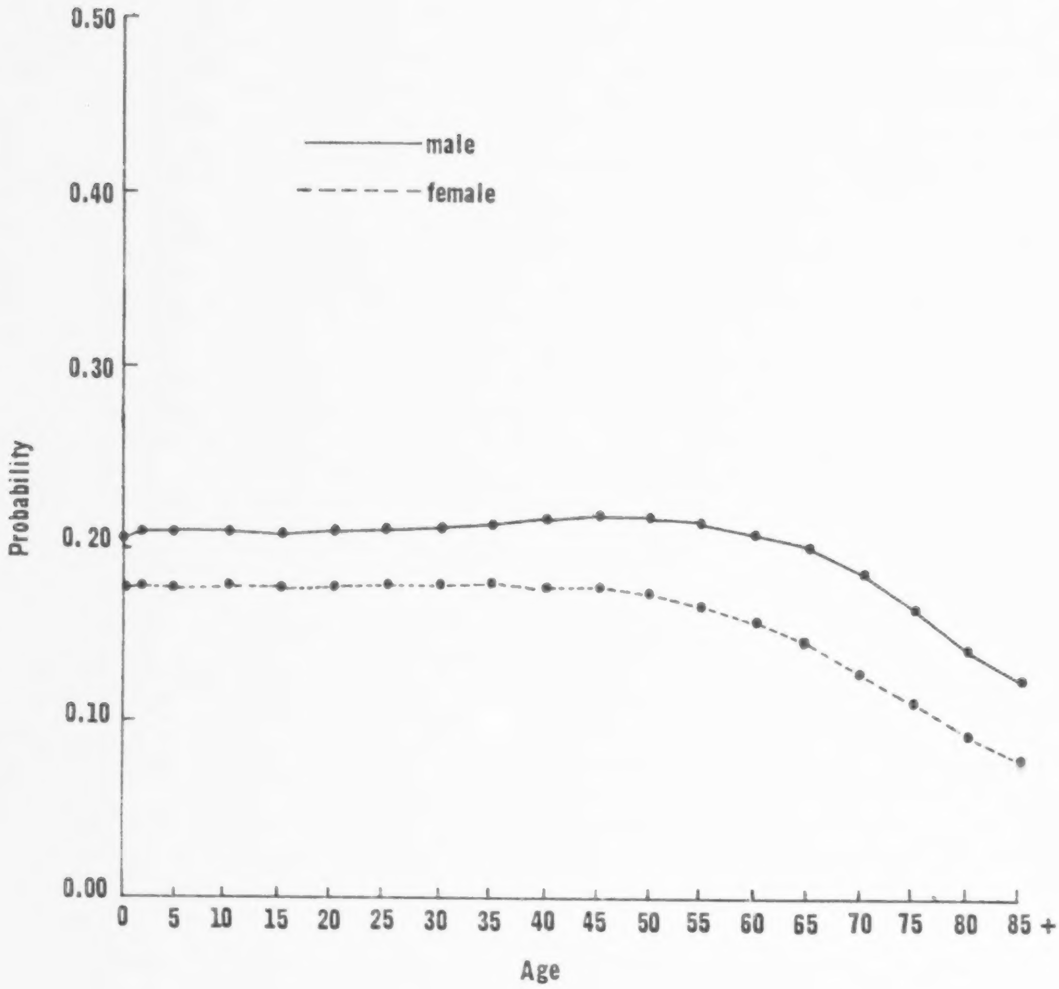
FIGURE 2.15 - Probability of Eventually Dying from Cancer by Age and Sex , Michigan Residents, 1977-1979 [1]



---

[1] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

CEREBROVASCULAR DISEASE

Deaths due to cerebrovascular disease (stroke) numbered 6,067 in 1979 or 8.3 percent of the 73,480 total Michigan resident deaths. This is 6.9 percent fewer stroke deaths than were observed in 1978 (6,520 deaths). Of the total in 1979, 56.2 percent were to females.

The median age at death from stroke was 79 years (Table 2.18). The median age for females was 81 years, 5 years higher than that for males. Deaths for white persons due to cerebrovascular disease displayed median ages several years higher than those for other than white persons. The median age was 68 years for other than white males and 77 years for white males. The median was 73 years for other than white females. This was 8 years less than that for white females (81 years).

The cerebrovascular disease death rate was 65.9 in 1979. The rate for females (72.9) was significantly higher than the rate for males (58.6). The age-specific death rates recorded in Table 2.19 and displayed in Figure 2.16 indicate that rates for males and females were similar below age 55. The rates for both sexes increased markedly in the older age groups. Rates for males were above those of females from ages 40 through 84. For ages 85 and over the rate for females was above that for males. The crude death rate for females exceeded that for males because of the larger proportion of women in the high risk older age groups. The age-adjusted rate of 42.3 for males was 18.8 percent higher than the age-adjusted rate for females of 35.6 in 1979.

Cerebrovascular disease death rates by age and race from Table 2.19 are graphically displayed in Figures 2.17 and 2.18. Rates for other than white males and females were higher than comparable rates for white persons in all age groups below age 80 with sufficient events to calculate rates. The greatest relative differentials between rates for other than white persons and those for white persons were observed for ages 40-64 years, where the rates for other than white males and females were between 2 and 5 times the comparable rates for their white counterparts. These relative differentials progressively decreased in the older age groups. Rates for white persons were considerably higher than those for other than white persons beyond age 79. Although the crude rates for white males and females were respectively, 6.5 percent and 29.8 percent higher than rates for

other than white persons, age-adjusted rates indicate an opposite relationship. The cerebrovascular disease age-adjusted death rate for other than white males was 41.7 percent higher than that for white males while for other than white females the age-adjusted rate was 59.8 percent higher than that for white females.

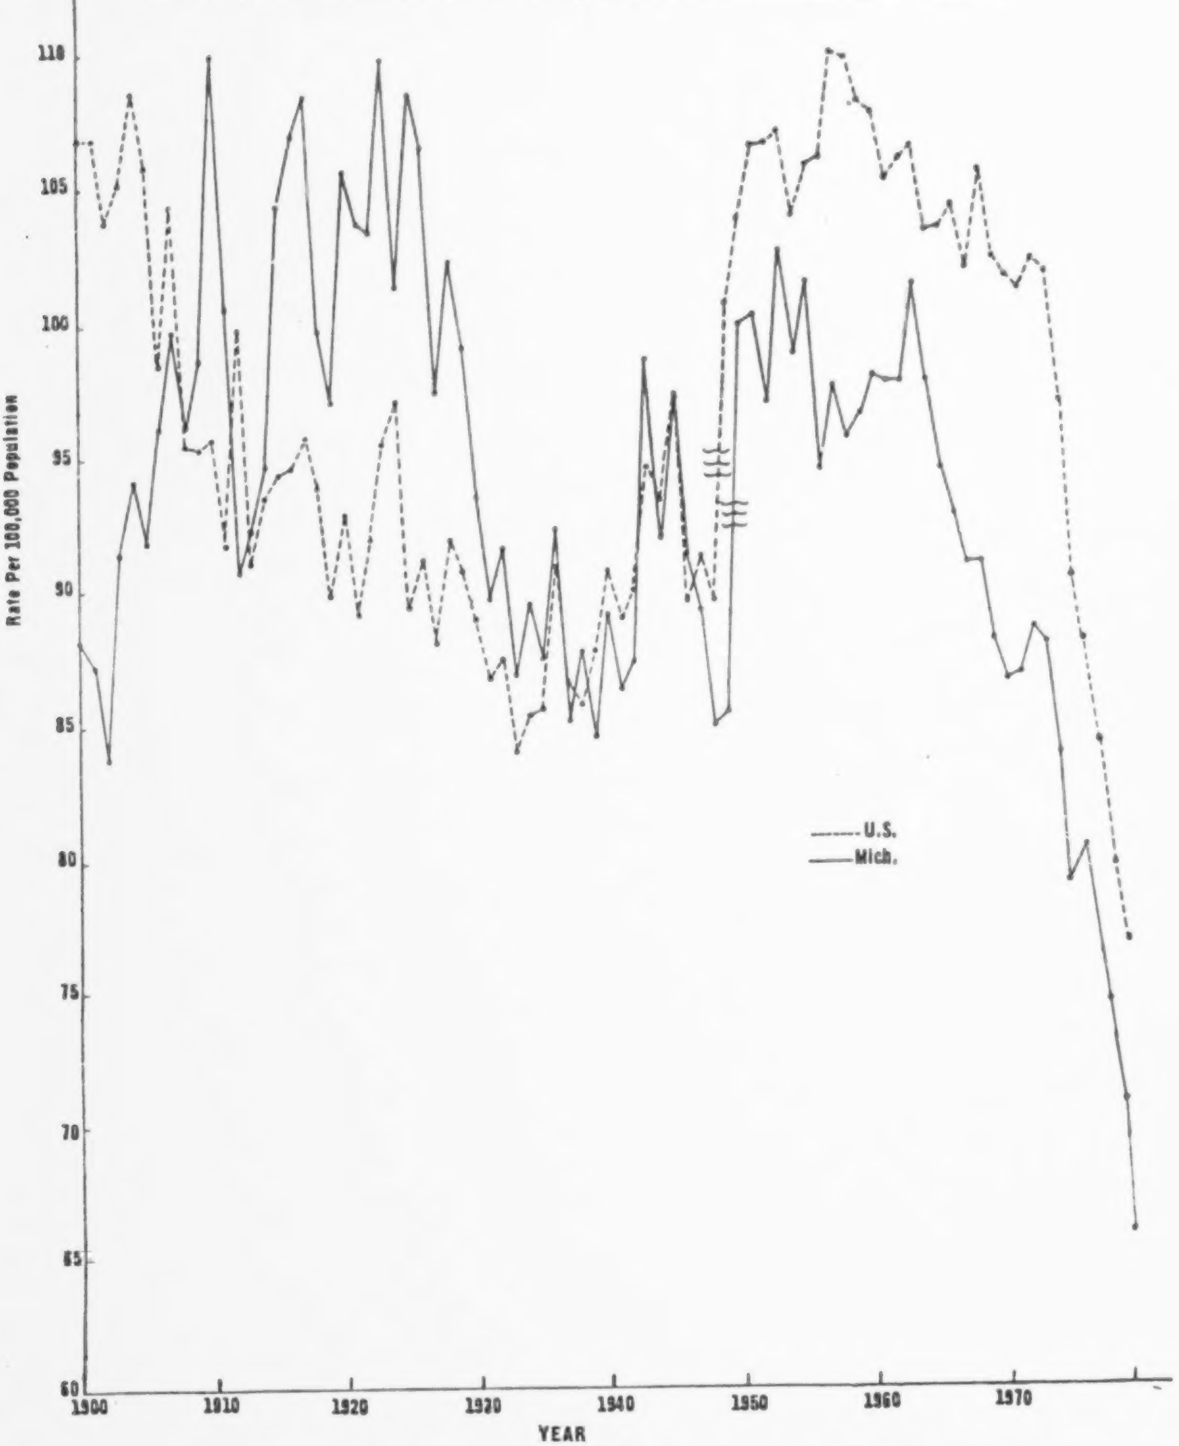
The historic pattern of cerebrovascular disease death rates has been one of strong variation (Figure 2.19). During the time period 1900-1949, the rates in Michigan ranged from a low of 83.9 in 1902 to a high of 110.0 eight years later. The national high and low rates for the years 1900-1948 were, respectively, 108.6 in 1904 and 84.1 in 1933. Rates for Michigan were below national rates from 1900 through 1907 but were generally, and sometimes markedly, higher from 1908 to 1938. Michigan and national rates were very similar over the next eight years, whereupon the Michigan rate slipped below the national rate and has so remained since 1946.

The 6th revision to ICD cause of death coding was adopted in the year 1949 nationally and 1950 in Michigan. This revision resulted in a lack of direct comparability between cerebrovascular disease death rates prior to these dates and those after adoption. Since the significant change in coding procedures in 1950, the cerebrovascular disease death rate in Michigan has ranged from 102.8 in 1953 to a low of 65.9 in 1979. Recent rates over the last sixteen years have shown a clear downward tendency both nationally and in Michigan. In 1979, the Michigan rate was 14.3 percent lower than the provisional United States rate of 76.9.

Age-adjusted rates for cerebrovascular disease deaths by race and sex are presented in Table 2.20. These rates have declined by approximately 40 percent since 1970 for each sex-race group in Michigan. Rates for other than white persons, however, remained substantially above rates for white persons throughout the period. Although Michigan and United States rates followed similar patterns, the state age-adjusted rates were generally lower than comparable national rates. This differential was especially marked for other than white males and females.

Acute but ill-defined cerebrovascular disease was most frequently given as the type of cerebrovascular disease causing death (2,647 deaths). Second in frequency was

FIGURE 2.19 - Cerebrovascular Disease Death Rates, Michigan and United States Residents,[1] 1900-1979[2]



[1] National rates are from death registration states for 1900-1932 and the United States for 1933-1979; United States rate for 1979 is provisional.

[2] The comparability of cerebrovascular disease death rates from the 5th revision of ICDA coding procedures with those of the 6th revision is considered weak. The comparability ratio is estimated to be 1.16. The 6th revision was adopted in 1949 for national cause-of-death statistics and in 1950 for Michigan Statistics. The comparability of cerebrovascular disease death rates through the 6th, 7th, 8th, and 9th revisions (1949 to date nationally and 1950 to date in Michigan) is high.

cerebral thrombosis and unspecified occlusion of cerebral arteries which caused 1,482 deaths in 1979 (Table 2.21). These two cause of death categories comprised 68.1 percent of all stroke deaths. Intracerebral and other intracranial hemorrhage was the third most frequent condition causing stroke deaths (771 deaths).

Based upon the mortality experience of 1977 through 1979 in Michigan, at birth a Michigan male faces a 0.079 chance of dying from cerebrovascular disease while the probability for a female at birth is 0.125. For both sexes the probability of eventual death due to this cause increases steadily with advancing age. At all ages females are more likely to eventually die from this cause than are males (Figure 2.20). This results primarily from the higher risks from competing causes for males. At age 60 probabilities for males start rising appreciably, reaching 0.125 by age 85. Data for females reveal a similar tendency, though the increase is somewhat less. The peak probability for females is 0.158 at age 85.

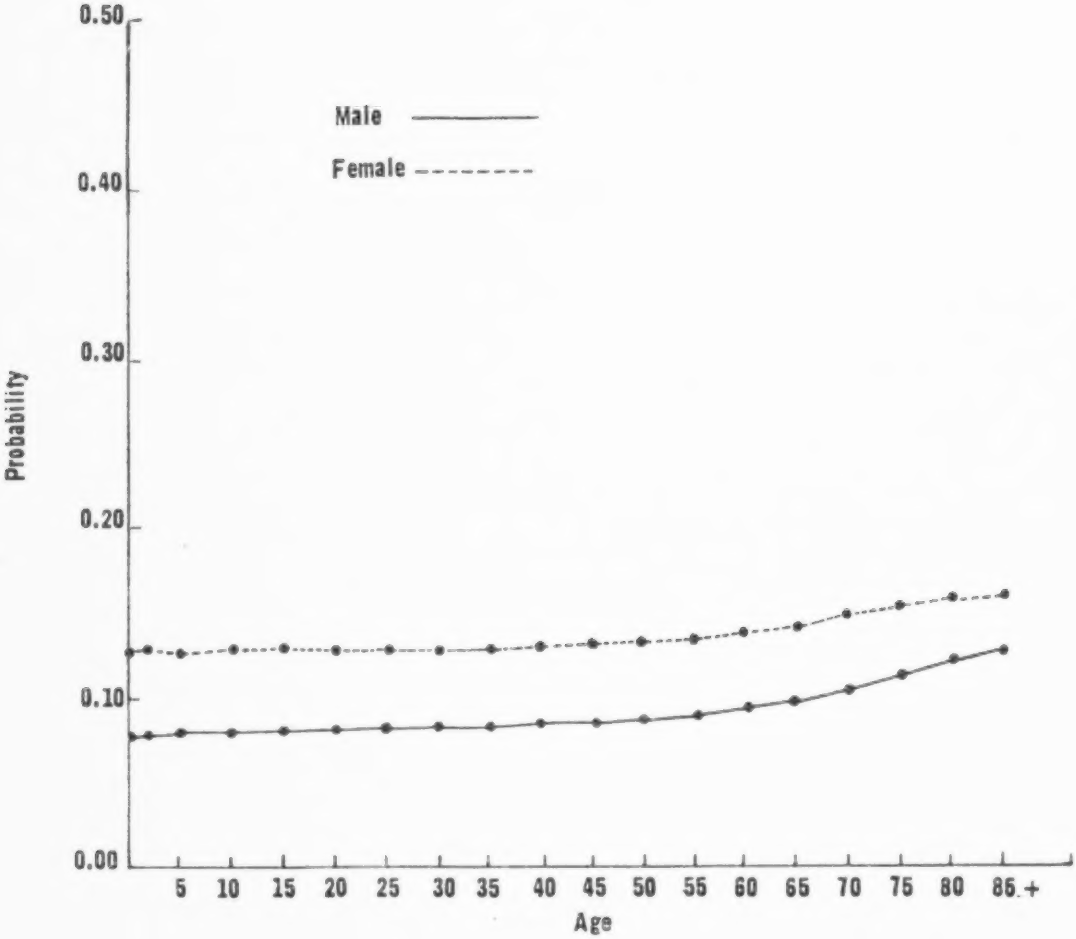
FIGURE 2.20 - Probability of Eventually Dying from Cerebrovascular Disease by Age and Sex, Michigan Residents, 1977-1979 [1]



[1] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

ACCIDENTS

About 5.2 percent of all Michigan resident deaths in 1979 were attributed to accidents. The total of 3,839 accidental deaths is 131 fewer than in 1978. The number of deaths from motor vehicle accidents was 1,967 in 1979, 171 fewer than in the previous year. In 1979 over two thirds (68.2 percent) of the total accidental deaths were to males, while 70.8 percent of the deaths from motor vehicle accidents were to males.

The median age at death among accident victims was 34 years (Table 2.22). The median age among males was 31, twelve years lower than the 43 year median for females. This differential is predominantly traceable to the relatively large number of accidental deaths of white males in the younger age intervals. The median age of accidental death for white males was 31 years compared to 36 years for other than white males. For white females who died from accidents the median of 45 years was 11 years higher than that for their other than white counterparts.

Accidental deaths among white males were especially concentrated in the 15-19 year and 20-24 year age ranges. These two age groups accounted for 29 percent of accidental deaths for white males compared to 20 percent or less for all other race/sex categories.

The crude death rate from accidents for males was more than twice as high as that for females. Age-specific accident death rates for males were greater than those for females in all age groups. The differentials between rates for males and females were greatest between ages 15 and 34. In the 25-29 age group, the rate for males was 4.9 times that for females. The age-adjusted death rate for males was 2.6 times that for females (Table 2.23).

Mortality rates by sex contained in Table 2.23 are displayed graphically in Figure 2.21. Although age-specific rates for males are generally much higher than those for females, the patterns of change are quite similar. Mortality rates for children between 5 and 14 years of age were somewhat lower than those for younger children. The rates then rose sharply for both sexes in the 15-19 age group. The rate for females reached an initial peak in the 20-24 year age group while the highest rate for males before age 70 occurred in the 25-29 age group. The rates for both groups generally decreased after this initial peak, remained fairly constant through age 64, and then increased

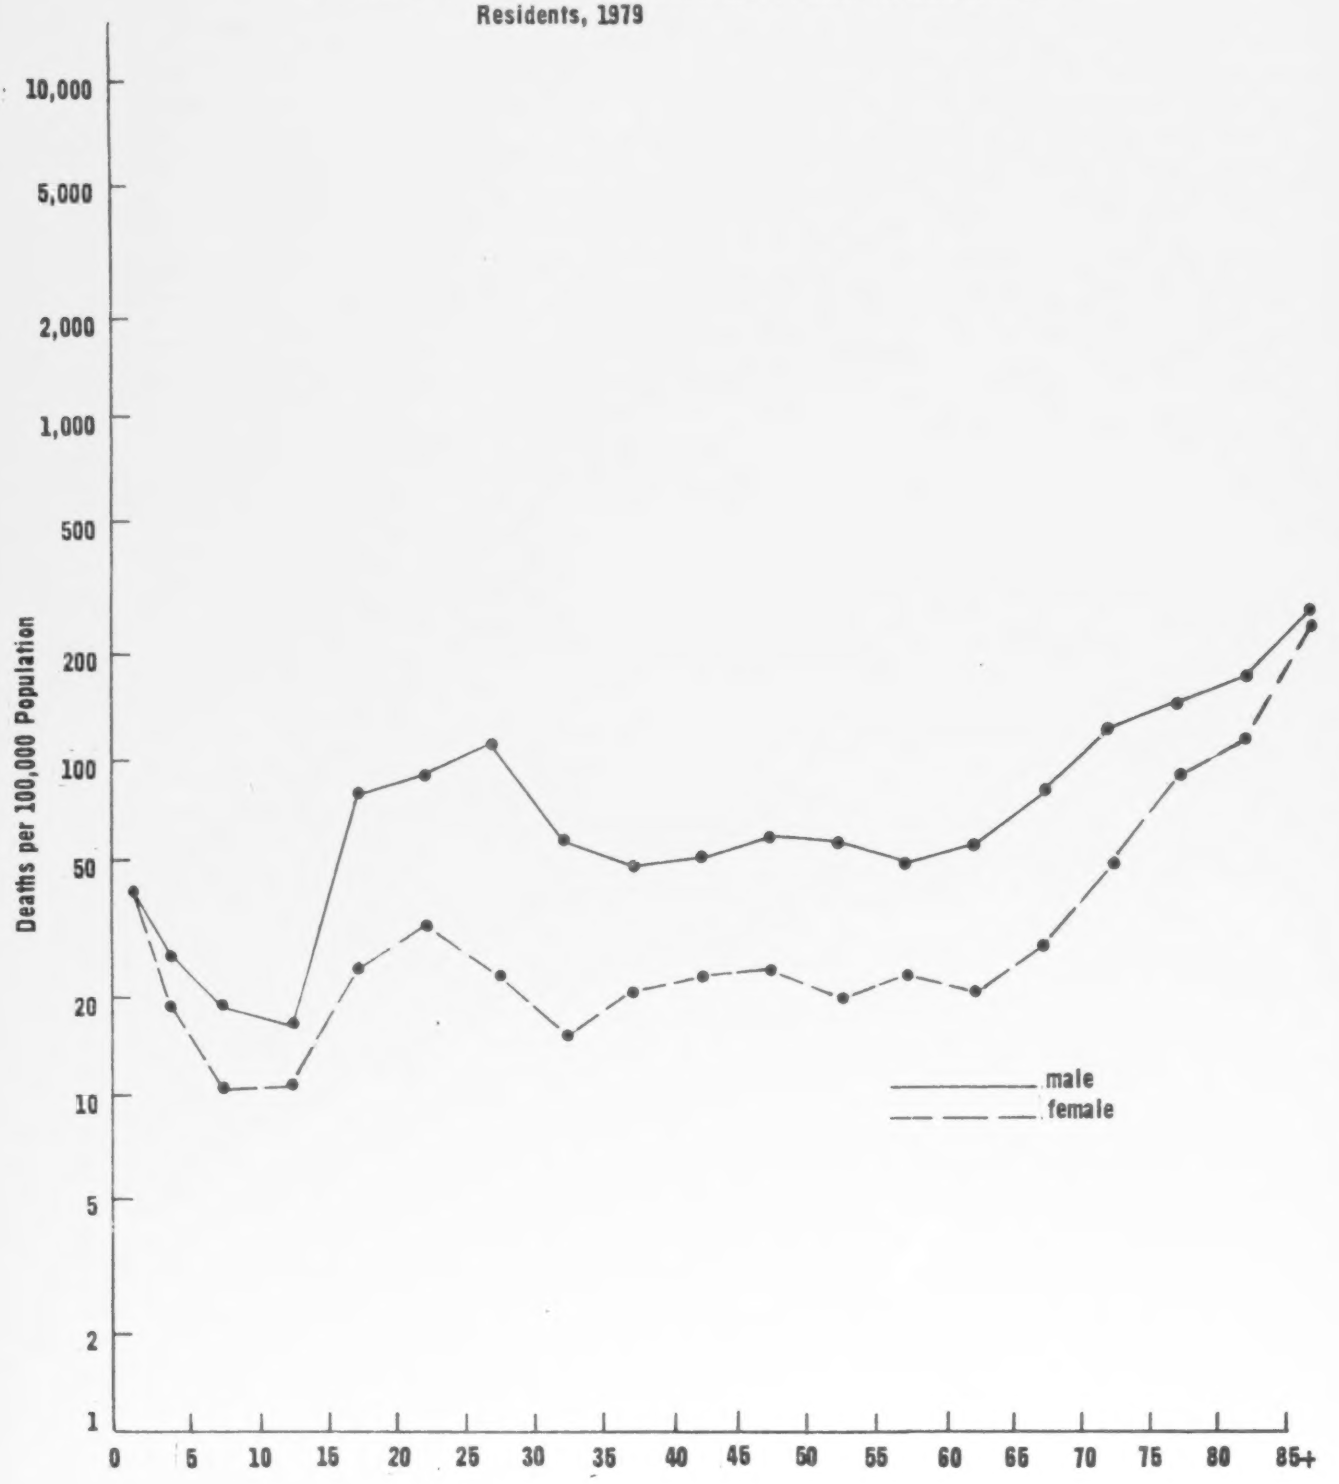
FIGURE 2.21 Age-Specific Accident Death Rates[1] by Sex, Michigan Residents, 1979



---

1 - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

continuously beyond that age. The differential in rates between males and females dropped steadily after age 69.

Accident death rates for white and other than white persons were quite similar. Crude rates for white persons were slightly higher than those for other than white persons. The age-adjusted rate for white males was slightly lower than that for other than white males, while for females the relationship was reversed (Table 2.23). Age-specific rates for white and other than white persons are graphically displayed in Figures 2.22 and 2.23. Rates for white males were higher than those for other than white males only from the 10-14 year age group through the 25-29 year age group. The pattern of age-specific rates for females was similar.

Michigan's accident death rate in 1900 was 71.9. The highest rate observed in this century was 103.1 in 1936, and the rate of 41.7 in 1979 is the lowest rate of the century. National rates have varied from 101.8 in 1907 to 46.9 in 1976. Michigan's rates have been below national rates fairly consistently since 1900. The last time Michigan's rate was above that of the United States was in 1955. The accident death rate for Michigan in 1979 was 12.9 percent below the provisional rate of 47.9 for the nation (Figure 2.24).

Michigan's age-adjusted death rates for accidental deaths were also below the comparable national rates in the 1970's (Table 2.24). The age-adjusted rates by race and sex declined for each population subgroup during this period. The most significant declines occurred in the rates for other than white persons. In Michigan the rate for all other than white persons was 19 percent higher than that for white persons in 1970 but only 2 percent higher in 1979. This differential declined nationally from 43 percent in 1970 to 21 percent in 1978.

Motor vehicle accidents involving collision with another motor vehicle was the largest single cause of accidental death in 1979, resulting in 816 deaths (Table 2.25). Deaths from all types of motor vehicle traffic accidents accounted for 1,910 deaths in 1979, a decrease of 9.0 percent from the 1978 total of 2,098 deaths. Accidental falls of all types resulted in 549 deaths in 1979. Accidents caused by fires and flames, accidental drownings, and accidental poisonings caused 266, 185, and 159 deaths respectively. Choking on food or

[1] List of 282 Selected Causes developed by the National Center for Health Statistics for tabulation of Mortality Data coded by the 9th Revision of the International Classification of Diseases, WHO.

other objects was the cause of 144 deaths, while misadventures during medical care, abnormal reactions, and late complications caused 64 deaths. Accidents caused by handguns and other firearms resulted in the death of 58 Michigan residents.

Of the total 3,839 accidental deaths, 1,972 or 52 percent occurred on streets and highways (Table 2.26). The second most common place of occurrence was the home with 800 deaths (21 percent). There were 72 accidental deaths at industrial places and premises, 69 at resident institutions, and 61 in public buildings. Note that the place of injury was not specified for 14 percent of the accidental deaths.

It can be seen from Figure 2.25 that the probability of eventually suffering accidental death is greater in the younger age groups than later in life. According to Michigan mortality data from the years 1977 through 1979 the probability of eventually dying from accidental causes is 0.047 for males and 0.027 for females at birth. Probabilities for males decline slowly through childhood and the teenage years, fall by nearly one third between ages 15 and 30, and thereafter decline more slowly. For females the probabilities decline more moderately and steadily. Probabilities for males remain much higher than for females until about age 55 and slightly higher after that age.

[1] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

CHRONIC OBSTRUCTIVE PULMONARY DISEASES AND ALLIED CONDITIONS

The fifth leading cause of death in 1979 was chronic obstructive pulmonary diseases and allied conditions. This group of diseases caused 1,934 Michigan resident deaths, of which 1,426 (73.7 percent) were to males (Table 2.27).

The median age at death of persons who died from these respiratory diseases was 72 years, slightly higher than the median of 71 years for deaths from all causes. However, unlike deaths from all causes where the median for females was substantially higher than for males (75 and 68), the median age of females who died from chronic obstructive pulmonary diseases and allied conditions was lower than that for males (70 years compared to 73 years). The median age for white persons (72 years) was five years higher than that for persons of other races (67 years).

The crude death rate for chronic obstructive pulmonary diseases and allied conditions was 21.0 per 100,000 population. The crude death rate for males was 2.9 times that for females (Table 2.28). Age-specific rates for males and females from Table 2.28 are graphically presented in Figure 2.26. The strong association between chronic obstructive pulmonary diseases and allied conditions and increasing age is clearly evident. Note also that age-specific rates for males are higher than those for females in all age groups. The relative differential between rates for males and females increases steadily with age through ages 75-79, where the rate for males is 6.3 times that for females. The age-adjusted death rate for this group of diseases was 3.4 times as high for males as it was for females (24.9 and 7.4 deaths per 100,000 population respectively).

Age-specific rates for white and other than white persons are displayed in Figure 2.27. Rates were higher for other than white persons prior to age 60, after which they were higher for whites. The age-adjusted death rate from these respiratory diseases for white persons was 26 percent above that for other than white persons.

Table 2.29 presents age-adjusted death rates by sex and race for the 1970's for deaths from this group of respiratory diseases. For the period 1970-1978 the rates are based on deaths from the 8th Revision ICDA categories of bronchitis, emphysema, asthma,

1978	15.3	24.7	8.1	15.5	25.1	8.4	13.0	21.0	6.1
1979	15.0	24.9	7.4	15.3	25.5	7.6	12.1	19.6	5.8

1 - Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see Technical Notes.

2 - Categories used for 1970-1978 are 8th Revision ICDA codes 490-493 (bronchitis, emphysema, and asthma) and *519.3 (chronic obstructive lung disease without mention of asthma, bronchitis, or emphysema). For 1979 the 9th Revision ICD codes are 490-496. See Table 2.6 for a description of comparability.

and chronic obstructive lung diseases without mention of asthma, bronchitis, or emphysema (ICDA 490-493, and *519.3). Data for 1979 and for this earlier period are not strictly comparable due to the introduction of the 9th Revision of the ICD in 1979 (see Table 2.7). The age-adjusted death rates for males remained fairly constant over the decade, while for females the rate in 1979 was 35 percent higher than in 1970. The increase in age-adjusted rates for females was due to an even larger increase (41 percent) in rates for white females, while the rate for other than white females was lower in 1979 than in 1970. The age-adjusted death rate for the total population of Michigan from chronic obstructive pulmonary diseases and allied conditions was 15.0 in 1979. This is 34 percent below the provisional United States rate of 22.7.

Of the 1,934 Michigan resident deaths due to chronic obstructive pulmonary diseases and allied conditions, 1,119 (57.9 percent) were classified as chronic airways obstruction, not elsewhere classified. An additional 19 deaths were attributed to bronchiectasis and extrinsic allergic alveolitis. These categories together are comparable to the 8th Revision title chronic obstructive lung disease without mention of asthma, bronchitis, or emphysema, to which 1,053 deaths were attributed in 1978. There were 537 deaths in 1979 due to emphysema, 146 due to bronchitis, and 113 due to asthma (Table 2.30).

Based on mortality data from 1977-1979, the probability of eventual death due to chronic obstructive pulmonary diseases and allied conditions is 0.036 for males and 0.014 for females at birth. The probability for males increases to a peak of 0.042 at age 65 and then declines in the last few age groups. The probability for females remains stable from birth through age 60 and then declines rapidly in the oldest age groups (Figure 2.28). Between ages 60 and 85 the probability for females declines by 50 percent to 0.007. It should be recalled that these probability estimates are based on mortality data which have been changing rapidly, in part due to changing diagnostic conventions.

TABLE 2.30 - Deaths Due to Chronic Obstructive Pulmonary Diseases and Allied Conditions by Specific Cause, Michigan Residents, 1979

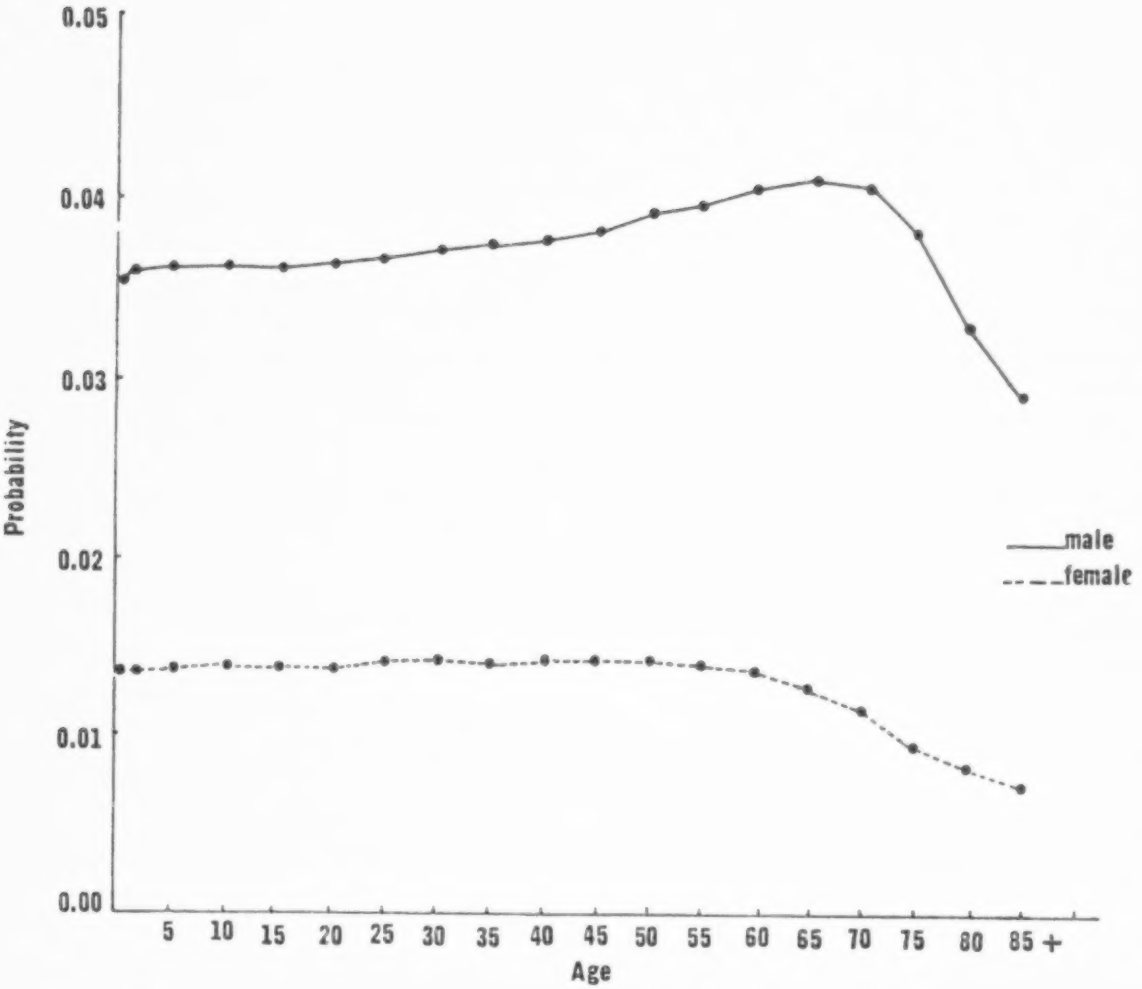
FIGURE 2.28 Probability of Eventually dying from Chronic Obstructive Pulmonary Diseases and Allied Conditions [1], by Age and Sex, Michigan Residents, 1977-1979 [2]



---

[1] Probabilities are based on deaths in 1977 and 1978 coded to 8th revision ICDA codes 490-493 and * 519.3, and deaths in 1979 coded to 9th Revision ICD codes 490-496.

[2] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

PNEUMONIA AND INFLUENZA

One of every 50 deaths that occurred to Michigan residents in 1979 was due to pneumonia and influenza. There were a total of 1,475 such deaths of which 786 (53.3 percent) were to males.

The overall median age at death in 1979 for those dying from pneumonia and influenza was 80 years (Table 2.31). This is well above the median age of 71 years for all deaths. The median age at death for white persons was significantly higher than that for other than white persons. The median age for white males (79) was 15 years greater than that for other than white males (64), while for white females the median of 84 years exceeded by 13 years that for other than white females. For persons of all races the median for males was 6 years less than for females.

The overall crude death rate for pneumonia and influenza deaths in 1979 was 16.0, compared to a rate of 21.8 in 1978. Part of the decline is due to the introduction of the 9th Revision of the ICD. The adjusted 1978 rate for pneumonia and influenza, which is the estimate of the rate which would result from coding deaths which occurred in 1978 by the 9th Revision of the ICD, is 20.2. The crude rate of 17.4 for males was 18 percent higher than the rate of 14.7 for females. On an age-adjusted basis, this differential increased significantly. The age-adjusted rate for males exceeded that for females by 74 percent (Table 2.32).

The age-specific death rates for males and females given in Table 2.32 are graphically displayed in Figure 2.29. Note the high pneumonia and influenza death rates for both sexes under 1 year of age. Pneumonia and influenza death rates increased rapidly beyond age 54 with rates for males significantly higher than for females.

The crude rates given in Table 2.32 indicate that a greater proportion of the white population died of pneumonia and influenza in 1979 than was the case for the other than white population. On an age-adjusted basis, however, the rate for the other than white group was 64 percent above that for the white group. Age-specific data indicate that the rates for the other than white population were higher from birth to age 80. For ages

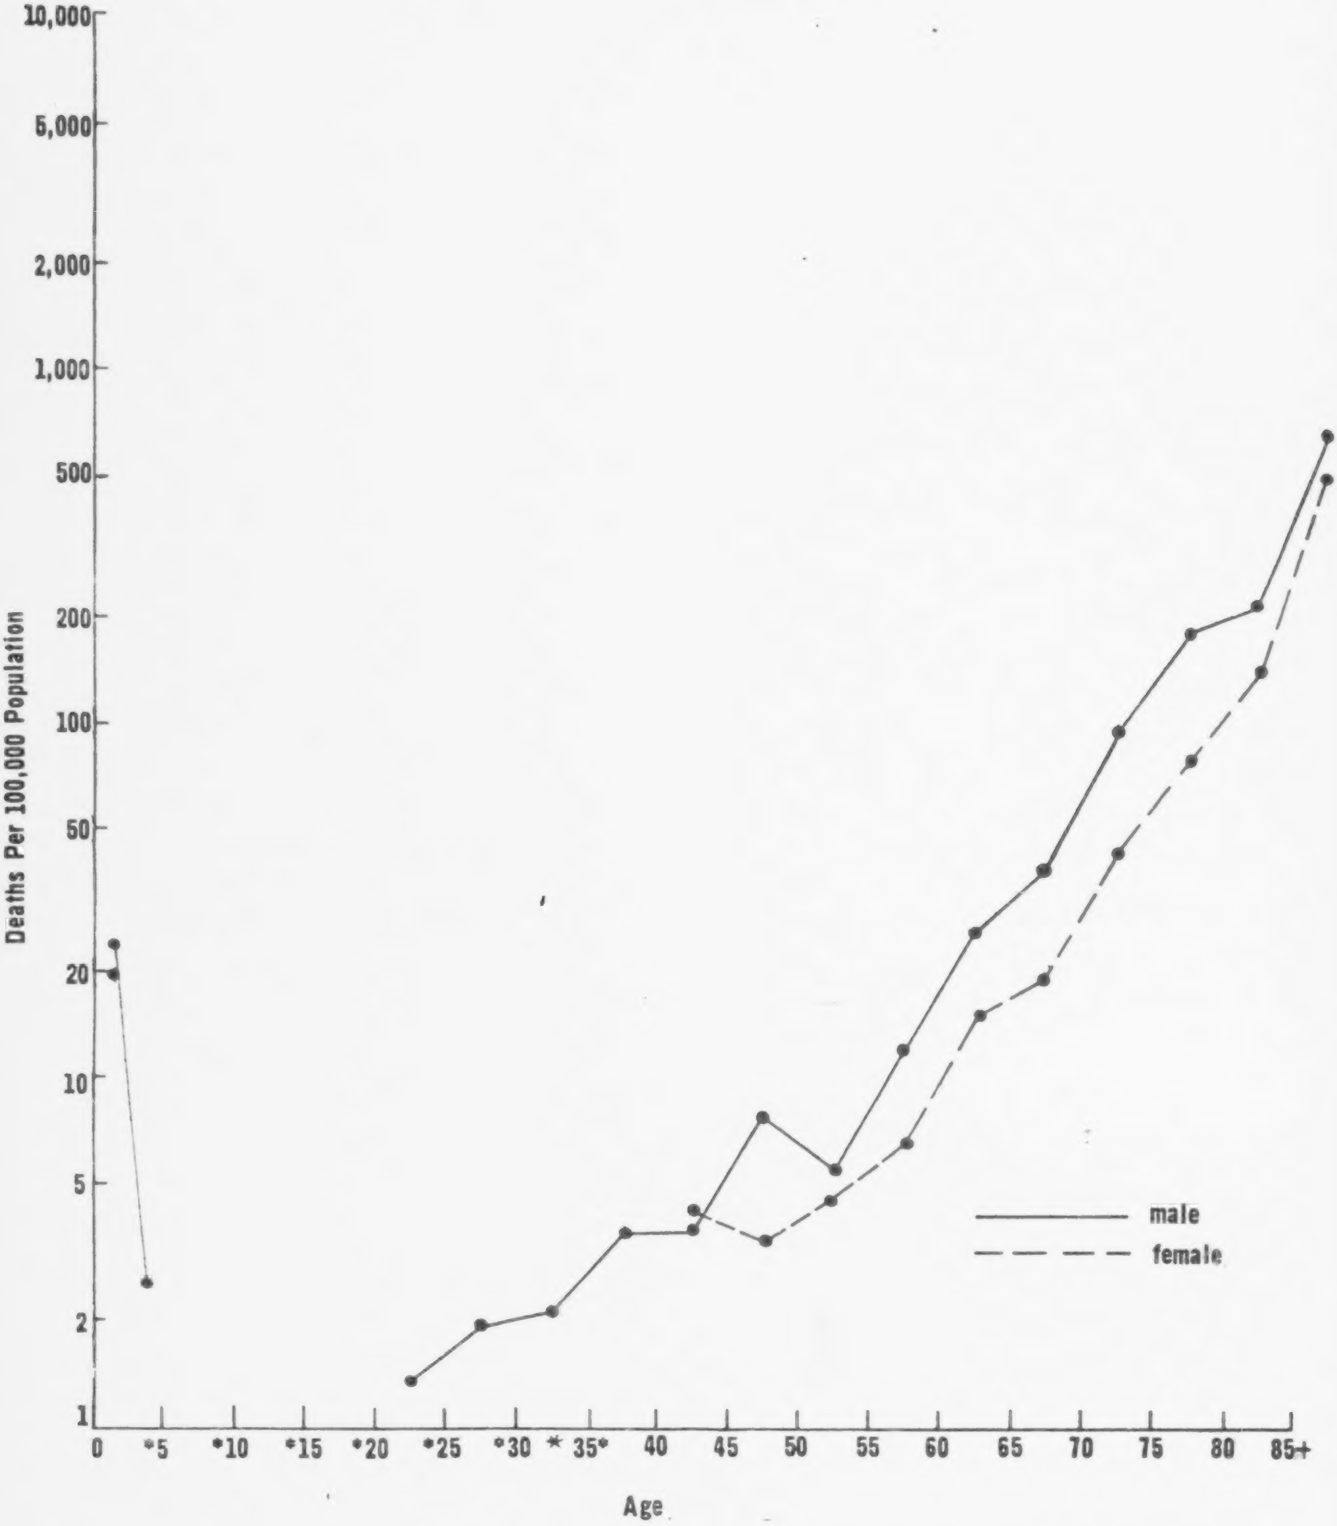
FIGURE 2.29 Age-Specific Pneumonia and Influenza Death Rates,[1] by Sex, Michigan Residents, 1979



1 - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

80 and above, pneumonia and influenza death rates were higher for white persons (Figure 2.30).

Pneumonia and influenza death rates have generally declined since 1900 both nationally and in Michigan (Figure 2.31). The annual rate was quite erratic from 1900 through 1940 or 1945. Since that time, the rate has been stable in terms of year to year variation. Michigan's rate of death due to this cause has been below the national rate almost without exception throughout this century. In 1900, the rate in Michigan was 120.3 while the national statistic was 202.1. The peak year for both was 1918 when the rates for the United States and Michigan were 588.5 and 399.8, respectively. In 1977 century low rates of 18.2 for Michigan and 23.7 for the nation were recorded. New low rates for the century were recorded in 1979 for both Michigan (16.0) and the United States (20.0). Although the change in coding classification makes the 1979 rates appear lower than if deaths had been coded by the 8th Revision of the ICDA used for years 1968-1978, the rates for both the state and nation were lower than comparable adjusted rates for 1977 (16.9 for Michigan and 22.0 for the U.S.).

Michigan's age-adjusted rates for pneumonia and influenza have generally been below those for the nation during the 1970's (Table 2.33). Between 1970 and 1979 the age-adjusted rate for Michigan declined by 52 percent. Rates for other than white persons declined more rapidly than rates for white persons. The decline was most dramatic for other than white females for whom the age-adjusted rate dropped from 30.8 in 1970 to 9.6 in 1979, a decline of 69 percent. The declines in rates for other than white males and females were more pronounced in Michigan than for the U.S.

The majority of deaths due to pneumonia and influenza were not attributed to a specific organism. Pneumonia due to other (7 deaths) and unspecified (1,040 deaths) organism accounted for 71.0 percent of all Michigan pneumonia and influenza deaths in 1979 (Table 2.34). Another 16.7 percent of the deaths were due to bronchopneumonia, organism unspecified, and 137 deaths were due to pneumococcal and other bacterial pneumonia (79 and 58 deaths respectively). The three most frequent categories of pneumonia and influenza deaths together accounted for 97.0 percent of all such deaths.

	1979	11.1 Pr.	---	---	---	---	---	---	---	---

1 - Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see Technical Notes.

2 - The introduction in 1979 of the 9th Revision of the International Classification of Diseases for coding causes of death resulted in substantial changes in this category, making trend comparisons difficult. The estimated comparability ratio for this category is 0.9264. Note that comparability ratios were developed for comparing crude death rates, and they are not strictly applicable for comparing age-adjusted death rates. For further discussion of comparability ratios see Qualifications and Limitations of Data and Calculations.

TABLE 2.34- Deaths Due to Pneumonia and Influenza by Specific Cause
Michigan Residents, 1979

282 LIST[1] NUMBER	CAUSE OF DEATH	NUMBER OF DEATHS	PERCENT

168	Influenza	21	1.4
	TOTAL	1,475	100.0

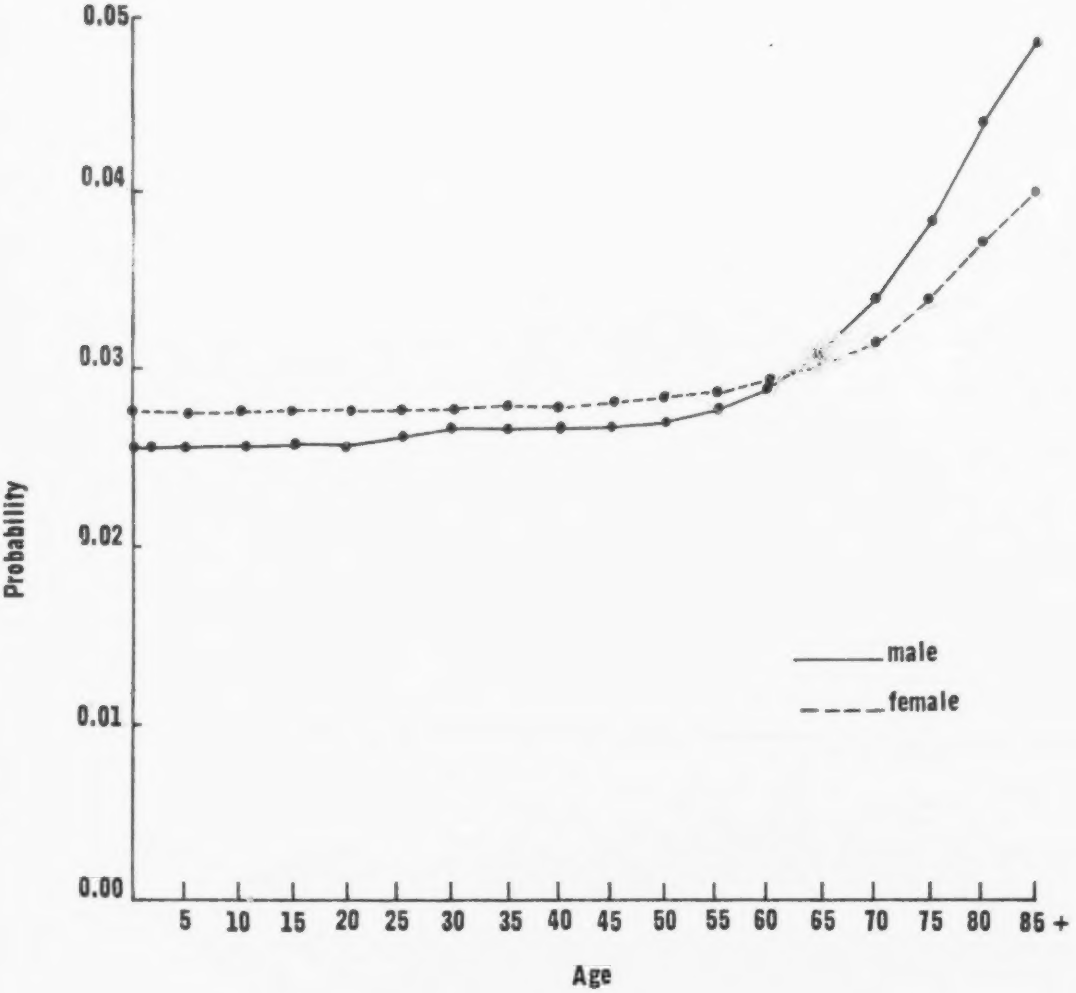
---

[1] List of 282 Selected Causes developed by the National Center for Health Statistics for tabulation of Mortality Data coded by the 9th Revision of the *International Classification of Diseases*, WHO.

Influenza was directly involved in 1.4 percent of all pneumonia and influenza deaths in 1979, compared to 8.7 percent in 1978 and 1.3 percent in 1977.

The likelihood of eventual death being caused by pneumonia and influenza is a stable 0.028 for females and between 0.026 and 0.027 for males from birth to age 50. The calculated probabilities for each sex slowly increase after this age, with probabilities for males increasing more rapidly than those for females. Based on the Michigan mortality experience of 1977-1979, by age 85 the chances of eventually dying from pneumonia and influenza are 0.048 for males and 0.040 for females (Figure 2.32).

FIGURE 2.32- Probability of Eventually Dying from Pneumonia and Influenza by Age and Sex, Michigan Residents 1977-1979[1]



---

[1] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

DIABETES MELLITUS

In 1979 diabetes mellitus caused the death of 1,449 Michigan residents. This is 102 fewer deaths than were caused by this disease in 1978. Deaths to females numbered 857 or 59 percent of all diabetes mellitus deaths. There were 592 diabetes mellitus deaths to males in 1979.

The median age at death for persons dying from diabetes mellitus was 73 years (Table 2.35). This is two years above the median age of all deaths. Males dying from this disease had a median age of 71 years whereas the median for females was 75 years. The median for white males was 71 years compared to 76 for white females. For other than white males the median was 68 years and that for other than white females 69 years.

Diabetes mellitus death rates by age, race, and sex are presented in Table 2.36. The diabetes mellitus crude death rate was 15.7 in 1979. The crude rate for females was 18.3, about 40 percent higher than the rate of 13.1 for males. When age-adjusted rates are examined, however, this differential in rates by sex is greatly diminished. The age-adjusted rate of 11.1 for females was slightly above that of males (10.5).

Age-specific mortality rates for males and females in Table 2.36 are graphically displayed in Figure 2.33. Rates were similar for males and females, and increased steadily with advancing age. Rates for both sexes were below 10 per 100,000 to age 50. At ages above 59 years, rates for females were higher than for males. The greatest differential was in the oldest age group where the rate for females exceeded that for males by 53 percent.

Although the crude diabetes mellitus death rate for white persons was somewhat above that of other than white persons (16.0 compared to 14.0), the age-adjusted rate for the other than white population was 32 percent higher than that for the white population. This differential is due to an elevated rate for other than white females. The age-adjusted rate for this group was 74 percent above that of their white counterparts. The age-adjusted rate for other than white males was 10 percent below that of white males.

Age-specific rates for other than white persons were higher than for white persons in all age groups below age 80 with a sufficient number of events to calculate rates

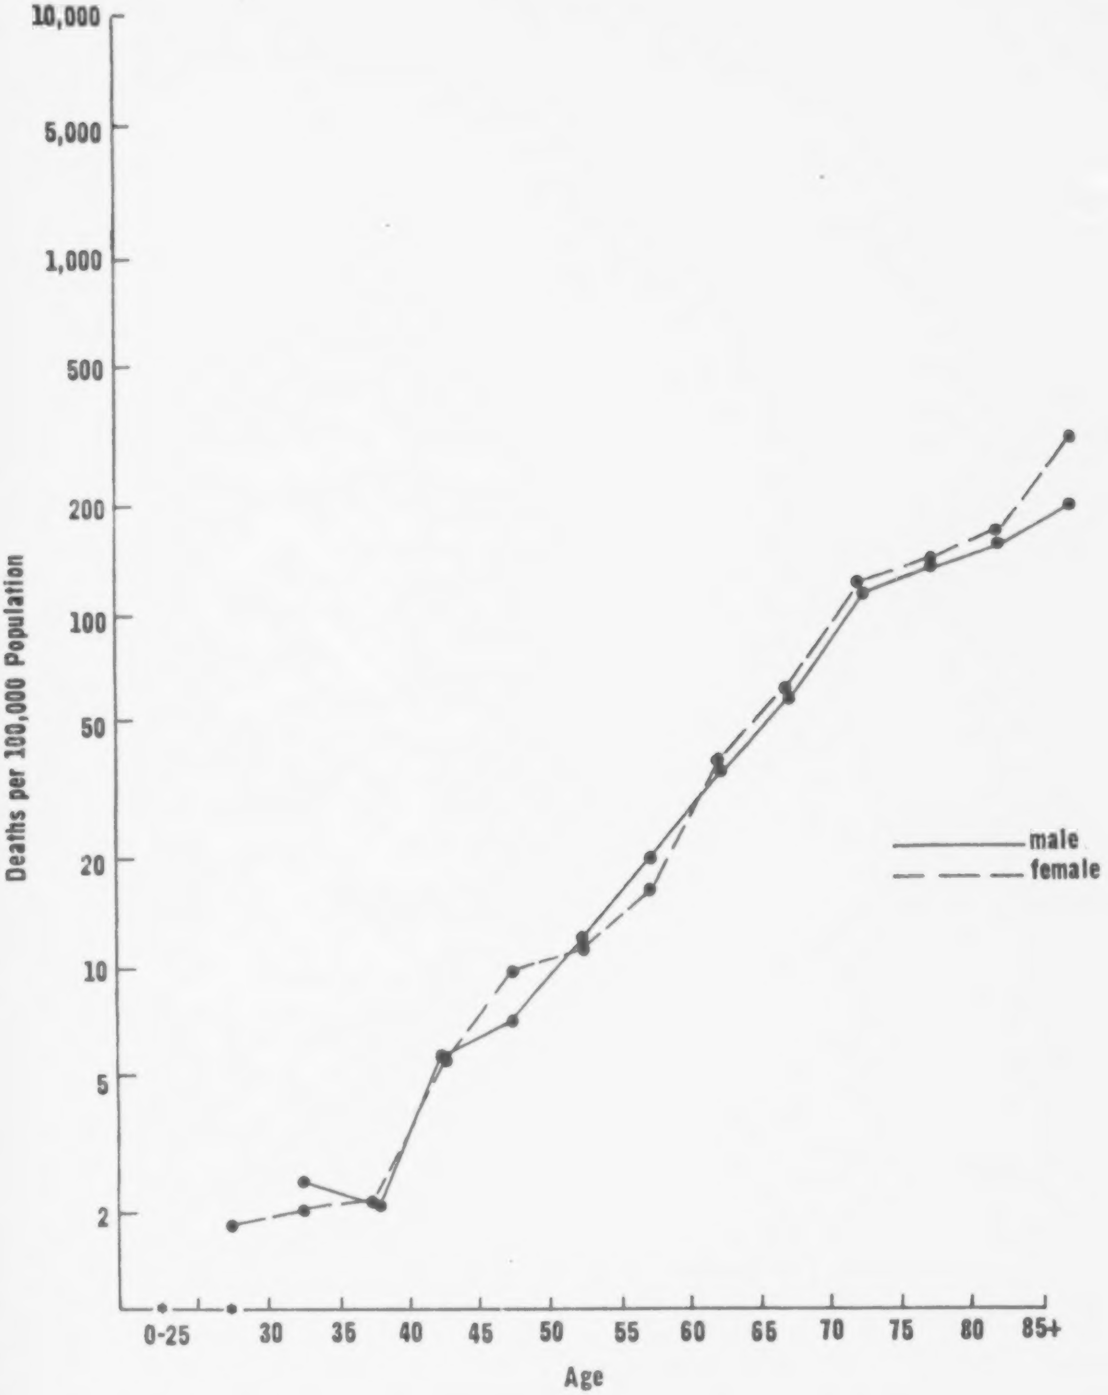
FIGURE 2.33 Age Specific Diabetes Mellitus Death Rates [1], by Sex, Michigan Residents, 1979



---

1 - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

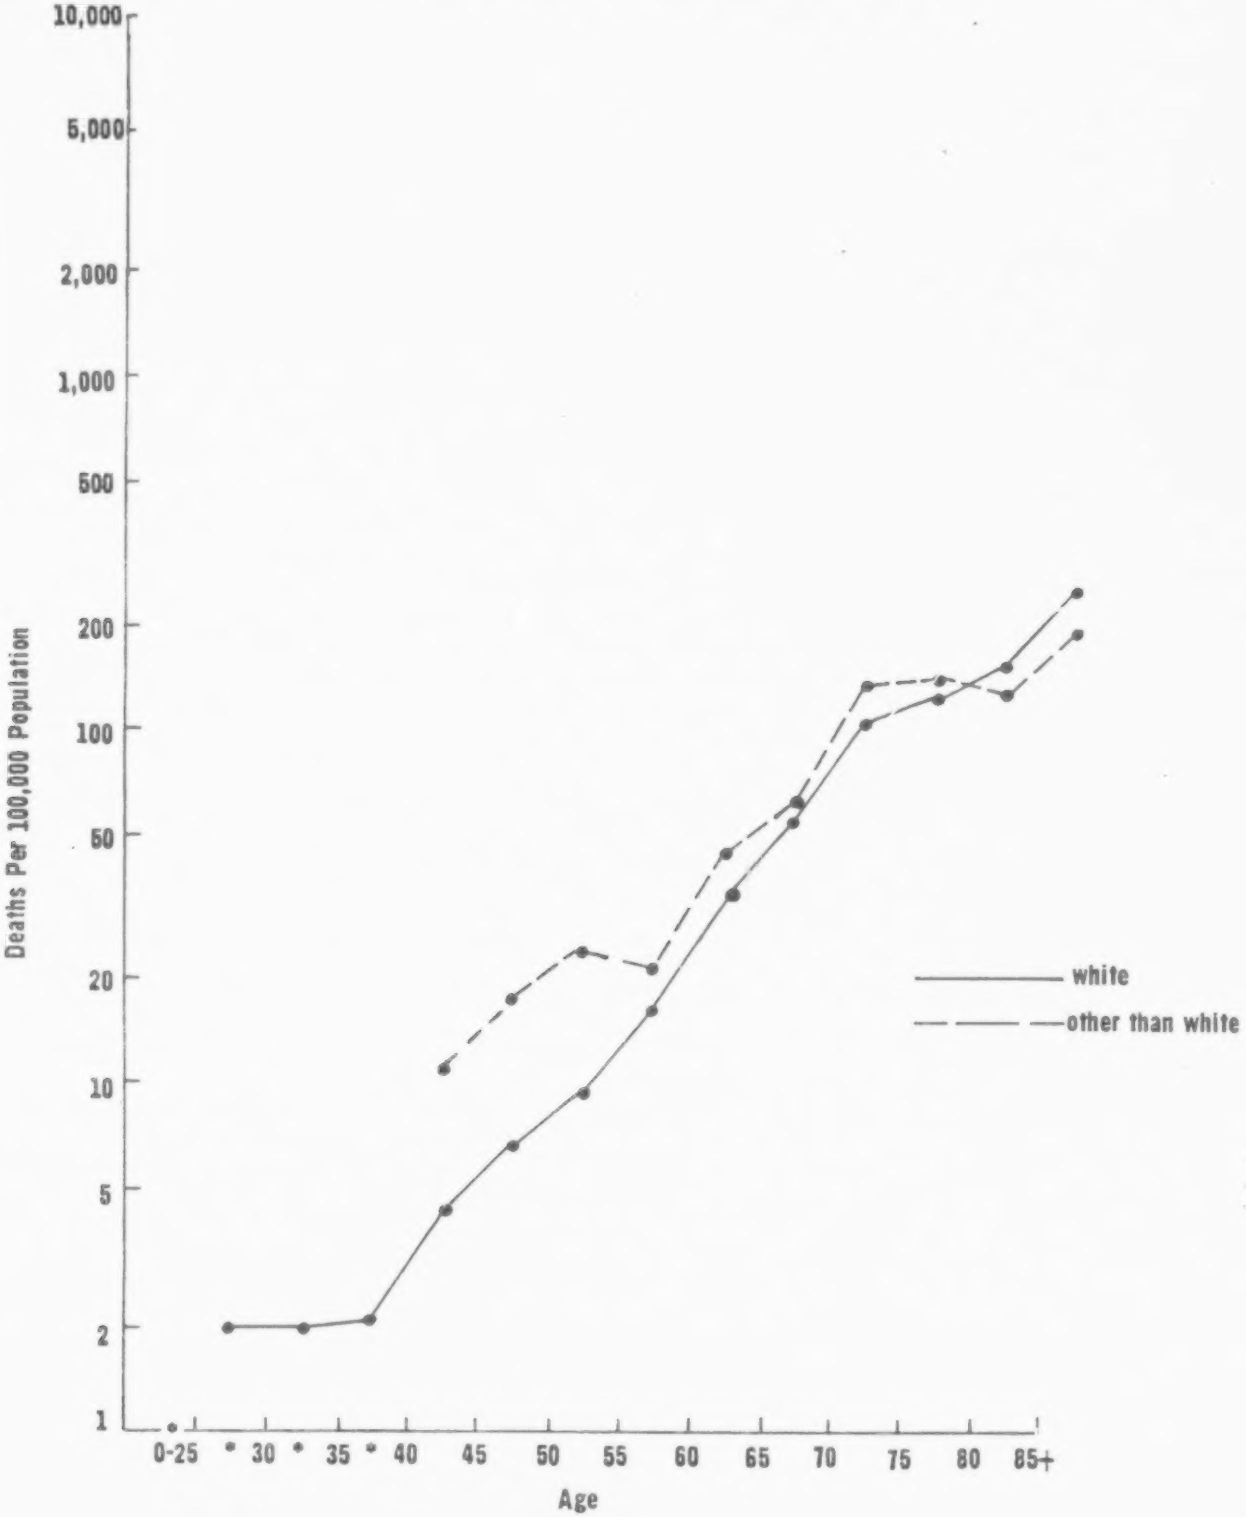
(Figure 2.34). The greatest relative differentials occurred for ages 40 through 54. Rates for other than white females were consistently above those for white females for ages 45 through 79 years (Table 2.36).

Diabetes mellitus death rates in Michigan rose steadily from a low of 9.3 in 1900 to a peak of 29.7 in 1949 (Figure 2.35). Adoption of the 6th revision of the International Classification of Diseases in 1950 caused a significant change in Michigan diabetes death rates. From 22.6 in 1950 the rate dipped somewhat then rose to a peak of 27.0 in 1966. Since then the rate has declined 42 percent to 15.7 in 1979. This is the lowest rate since the 6th revision of the ICD was adopted in 1950, and is 7.1 percent below the 1978 rate of 16.9. The decline in 1979 is the seventh consecutive annual decline in the diabetes mellitus death rate. The national ranges in the first half of this century were from 11.0 in 1900 to 18.3 in 1948 (the year of the adoption of the 6th revision nationally was 1949). The rate for the nation since 1949, though more stable than Michigan's rate, has tended to follow the same pattern. A peak of 19.2 was reached in 1968. Since that time the rate for the nation has declined by 22 percent to a provisional 15.0 in 1979. This is also a record low for the United States since 1949, and represents a decline of 3.2 percent from the rate of 15.5 for 1978.

The diabetes mellitus death rate for the nation was generally above Michigan's rate for the first 25 or so years in this century. Since 1942, Michigan's rate has been above that of the nation. Through the 1960's the differential between the rates for Michigan and the United States was quite large. This has only recently started to diminish. In 1979 Michigan's rate (15.7) was 4.7 percent above the provisional estimate of 15.0 for the United States.

Age-adjusted death rates for diabetes mellitus in the 1970's are presented in Table 2.37. These rates have generally declined both in Michigan and the United States for all population groups. The rate for the total population of Michigan has declined by 46 percent since 1970, and has fallen each year since 1972. The rate for the U.S. has declined each year, falling by 30 percent over the decade. In Michigan, rates for other than white persons experienced a greater absolute and relative decline than those for

Figure 2.34 Age-Specific Diabetes Mellitus Death rates[1], by Race, Michigan Residents, 1978



[1] - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

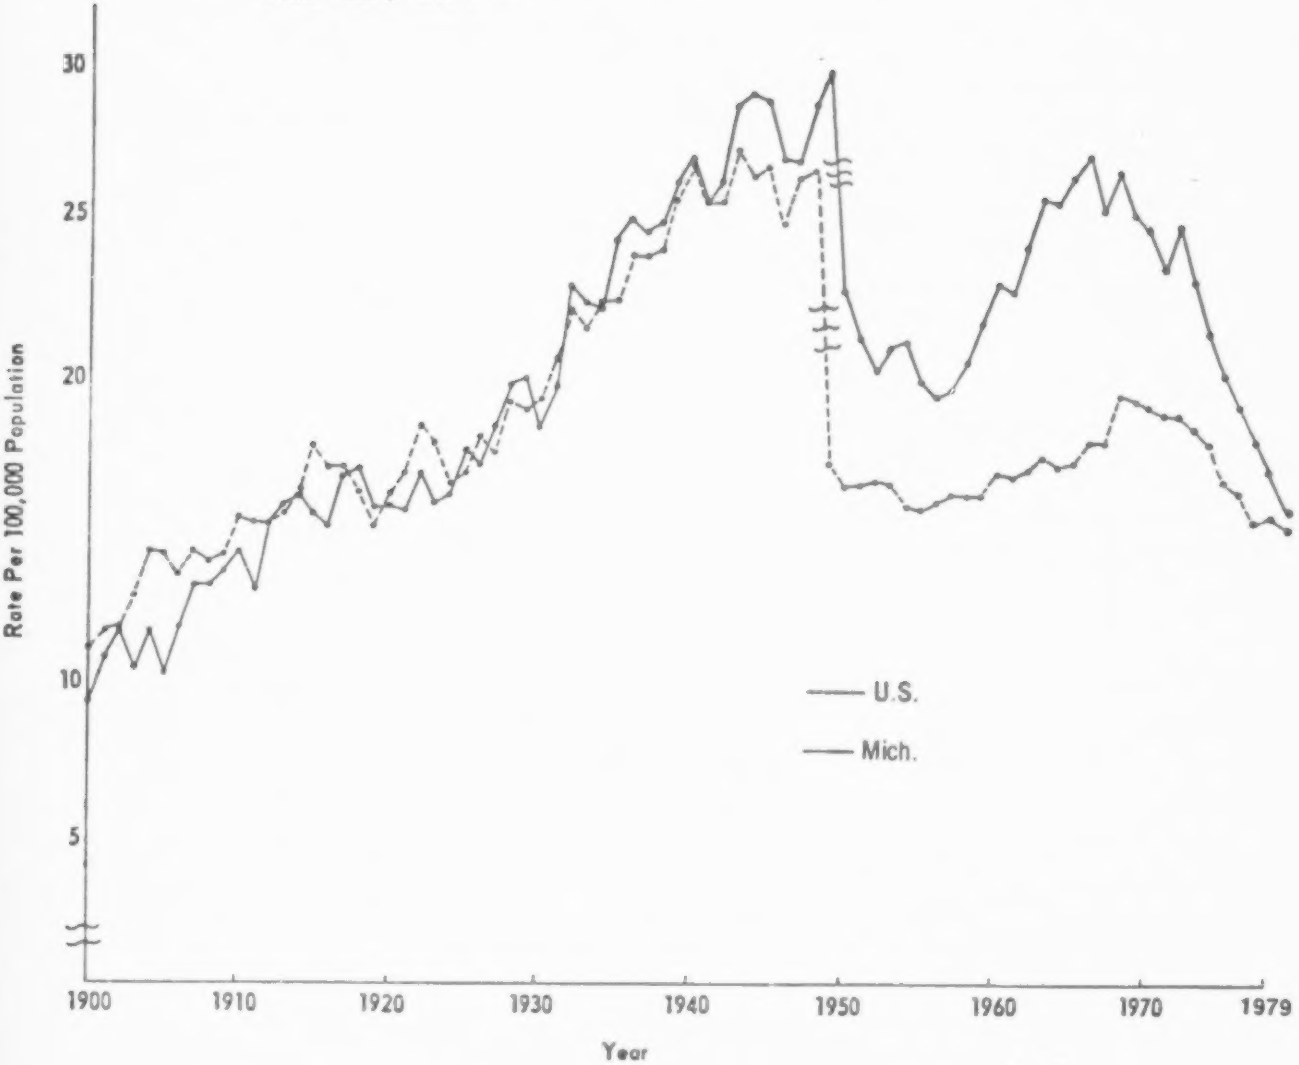
FIGURE 2.35 —Diabetes Mellitus Death Rates, Michigan and United States,[1] 1900-1979[2]



[1] National rates are from death registration states for 1900-1932 and the United States for 1933-1979,; U. S. rate for 1979 is provisional.

[2] The comparability of diabetes mellitus death rates from the 5th revision of the ICDA coding procedures with those of the 6th revision is considered weak. The comparability ratio is estimated to be .55. The 6th revision was adopted in 1949 for national cause-of-death statistics and in 1950 for Michigan statistics. The comparability of diabetes mellitus disease death rates through the 6th, 7th, 8th, and 9th revisions (1949 to date nationally and 1950 to date in Michigan) is high. General comparison before and after these dates of adoption can be made but detailed study requires special consideration. See Technical Notes.

[1] - Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see Technical Notes.

white persons. At the beginning of the decade age-adjusted rates for other than white males were almost 50 percent above those for white males. In 1979 the rate for other than white males dipped below that of white males. In 1970 the rate for other than white females was over twice that of white females. This differential was still 74 percent in 1979.

The declines in the age-adjusted rates for other than white persons were much greater in Michigan than those observed for these groups nationally. Michigan's rates for other than white persons were substantially higher than comparable rates for the nation in 1970, but have been about the same as those for the nation since 1974. Age-adjusted rates for white persons in Michigan also declined more sharply than comparable rates for the nation. However, they remained higher than those of the nation throughout the period.

In 1979 76.1 percent of all diabetes mellitus deaths were without mention of complication. Diabetes with peripheral circulatory disorders caused 93 deaths, while diabetes with renal manifestations was the cause of an additional 81 deaths. There were 131 deaths in 1979 where acidosis or coma was mentioned with the disease. These are deaths where a diabetic crisis was involved (Table 2.38).

At birth, the probability of eventual death due to diabetes mellitus is 0.016 for males and 0.027 for females (Figure 2.36). The probability of death from diabetes mellitus for females increases slightly from birth to age 60 and declines after that age. Females are less likely to eventually die from this cause at ages 75 and over than when they were born. Although probabilities for males are consistently below those for females, the pattern of change is similar to that for females. The peak probability for males is 0.017 at age 65.

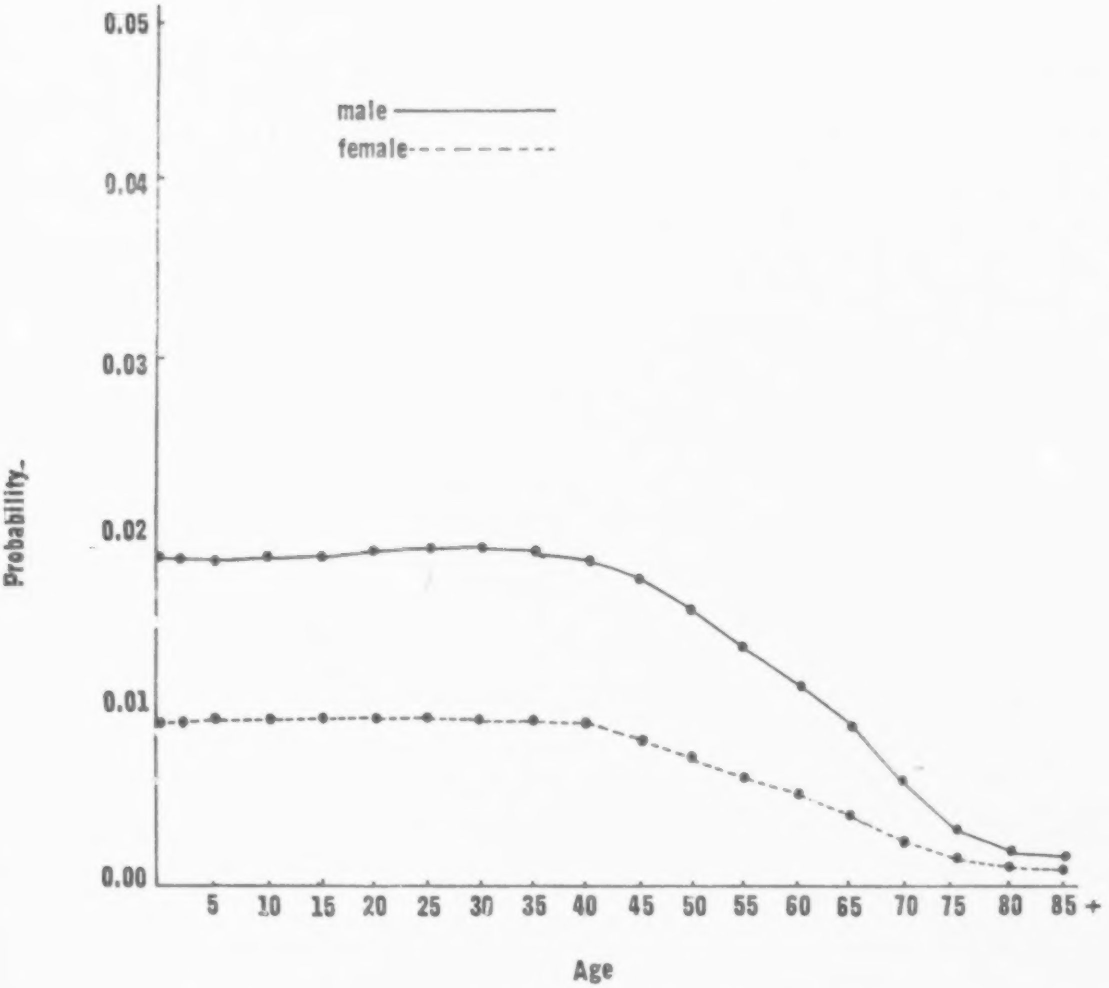
FIGURE 2.40 - Probability of Eventually Dying from Chronic Liver Disease and Cirrhosis[1] by Age and Sex, Michigan Residents 1977-1979[2]



[1] This category was termed cirrhosis of the liver in 1977 and 1978.

[2] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

ATHEROSCLEROSIS

There were a total of 1,173 Michigan resident deaths attributed to atherosclerosis in 1979, making this cause the 9th leading cause of death in the state. (Atherosclerosis is the 9th Revision term for the category most nearly comparable to arteriosclerosis under the 8th Revision). Six out of every ten deaths due to this cause in 1979 were to females, while 44.7 percent of all deaths were to females. Only 73 of the 1,173 deaths were to other than white persons. This is 6.2 percent of all atherosclerosis deaths, while 12.8 percent of all deaths were to other than white persons.

The majority of the atherosclerosis deaths were to persons of advanced ages. The median age of all deaths resulting from this disease was 84 years. The median age at death for males was 4 years lower than for females, and the median for other than white persons was 7 years lower than for white persons (Table 2.43).

Atherosclerosis resulted in 12.7 deaths per 100,000 Michigan residents in 1979. Although this is slightly higher than the rate of 12.5 observed for arteriosclerosis in 1978, the apparent increase is wholly due to the change in coding classification from the 8th Revision ICDA to the 9th Revision ICD (see Table 2.7). The 1979 rate of 12.7 is actually 4.5 percent below the adjusted 1978 rate of 13.3.

Deaths to females from this disease were relatively more frequent than for males with crude mortality rates of 15.0 and 10.4 respectively (Table 2.44). The age-adjusted rate for males, however, was 17 percent higher than that for females. Age-specific atherosclerosis death rates rose sharply beyond age 69 for persons of both sexes. Rates for males were generally at or above those for females, except in the oldest age group, where the rate for females exceeded by 23 percent that for males (Figure 2.41).

The crude rate for deaths due to atherosclerosis for white persons was 2.4 times that for other than white persons. However, when the differing age distributions of the two groups are considered, the differential is greatly reduced. The age-adjusted rate of 5.7 for whites is 21 percent above the rate of 4.7 for other than white persons. Age-specific rates were lower for white persons before age 70 and higher for white persons beyond age 79. The largest differential was observed in the oldest age group, where the

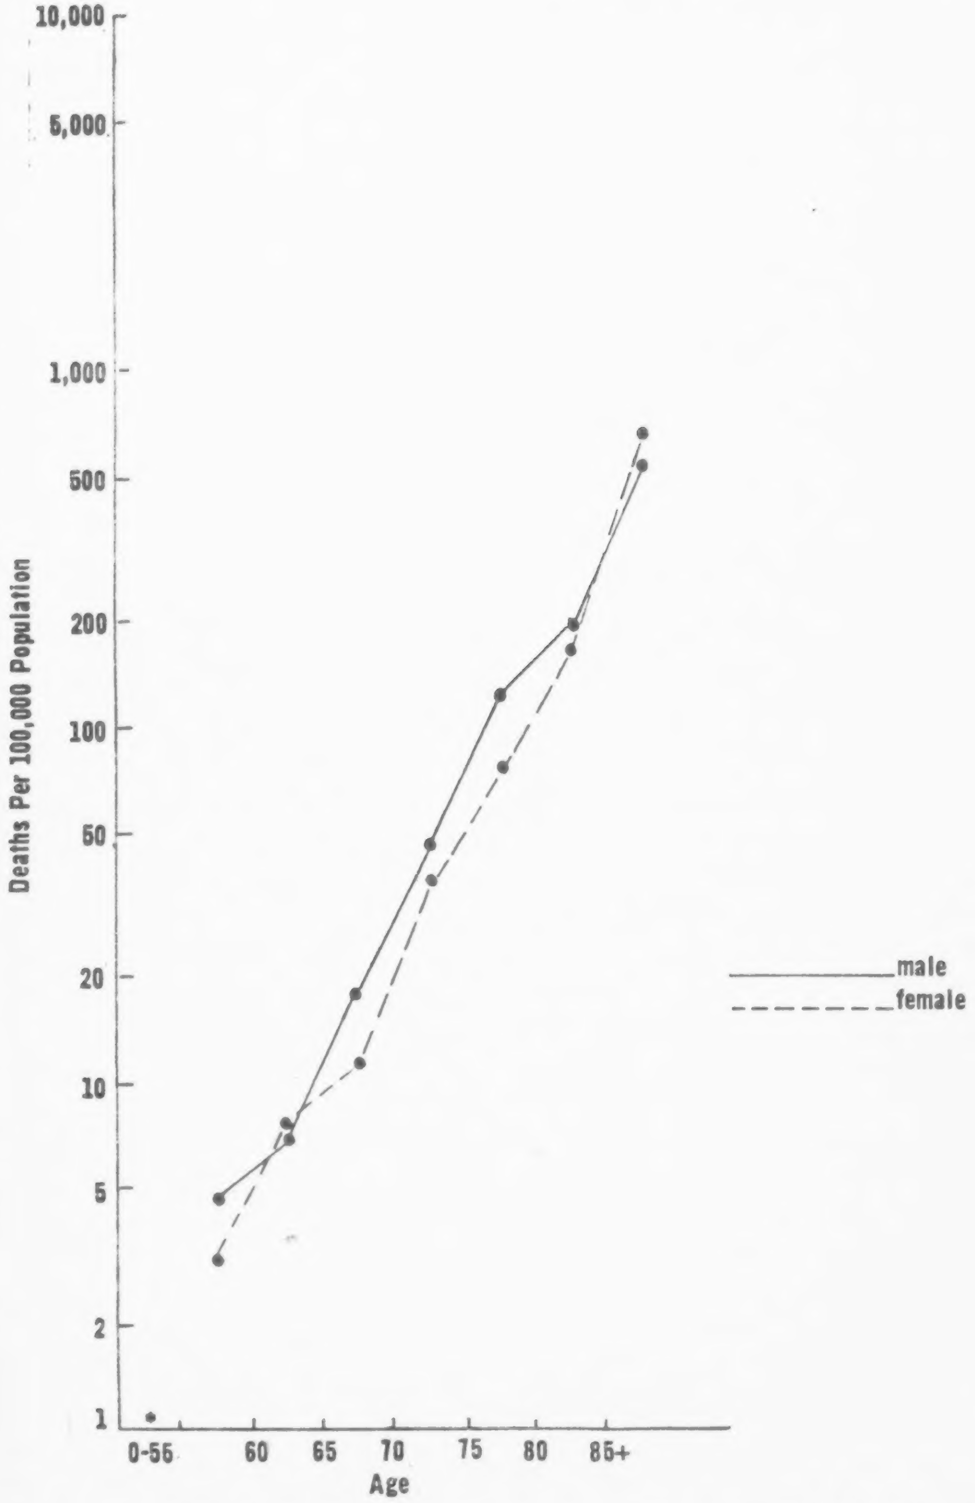
FIGURE 2.41 Age-specific Atherosclerosis Death Rates [1] by Sex, Michigan Residents, 1979



[1] - Note that death rates are shown on a logarithmic scale; vertical distances represent relative differences in rate rather than absolute differences.

rate for white persons was 3.2 times that of other than white persons (Figure 2.42).

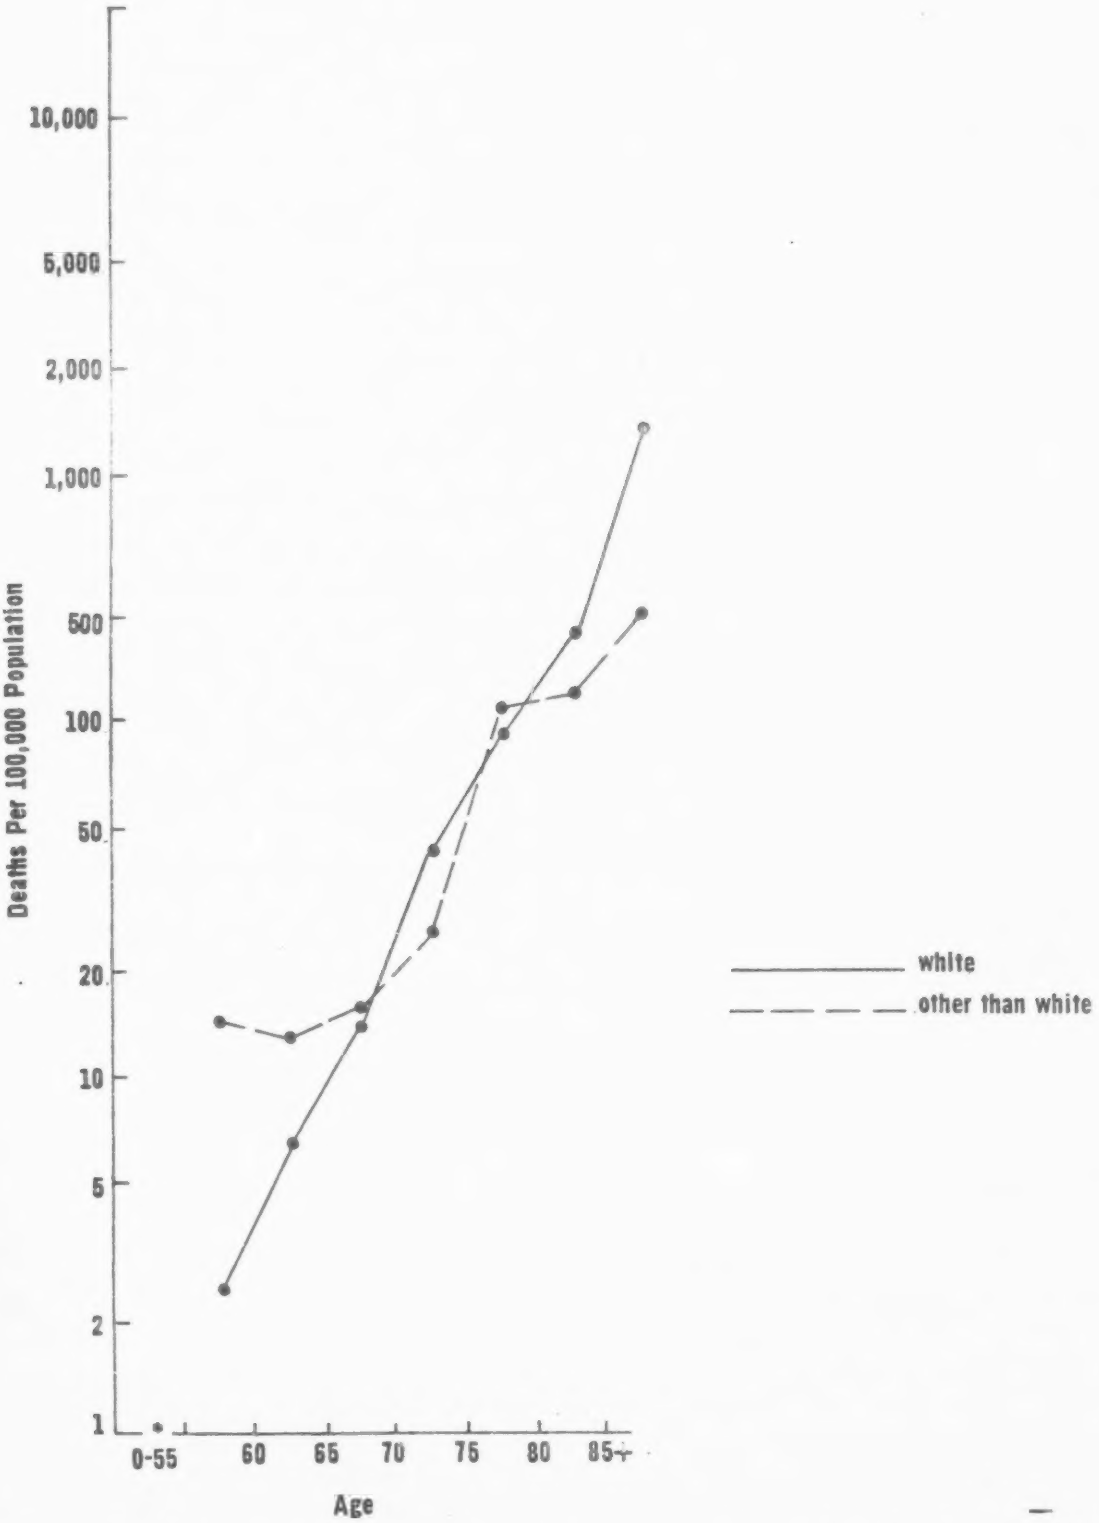
Inspection of arteriosclerosis death rates since 1900 is far less informative than study of the historical data for other causes of death. The classification of this disease has been significantly altered several times since the inception of the ICD codes (see footnote of Figure 2.43). What can be seen in Figure 2.43 is a strong rise from 1900 to 1912. Rates in Michigan and the nation then stabilized and began declining through 1929. A coding revision then breaks comparability with 1930 rates. The arteriosclerosis death rates from 1930 to 1948 show no clear direction. From 1949 to 1967 the rates for the nation held fairly stable while in Michigan the rates dropped and then returned to national levels. Since 1968 the death rates due to arteriosclerosis in Michigan have been below national rates.

Age-adjusted death rates have declined for all population groups in Michigan and the United States through the 1970's (Table 2.45). The rates for Michigan residents were generally lower than those for the nation, with Michigan's rates for other than white persons falling substantially below the comparable rates for the nation. Rates for other than white persons were markedly lower than those for white persons in Michigan and somewhat lower in the nation.

Nearly all atherosclerosis deaths are reported as generalized and/or unspecified as to type. Only 69 of the 1,173 deaths were in other classifications. Of these, 66 were attributed to atherosclerosis of arteries of the extremities (Table 2.46).

The 1977 through 1979 mortality data for Michigan indicate that females are more likely to eventually die from atherosclerosis than males. At birth, the likelihood for females is 0.028, while for males it is 0.015. These probabilities rise slowly through age 50 and increase rapidly beyond that age. By age 85, the probability of eventually dying from atherosclerosis is 0.050 for females and 0.042 for males (Figure 2.44).

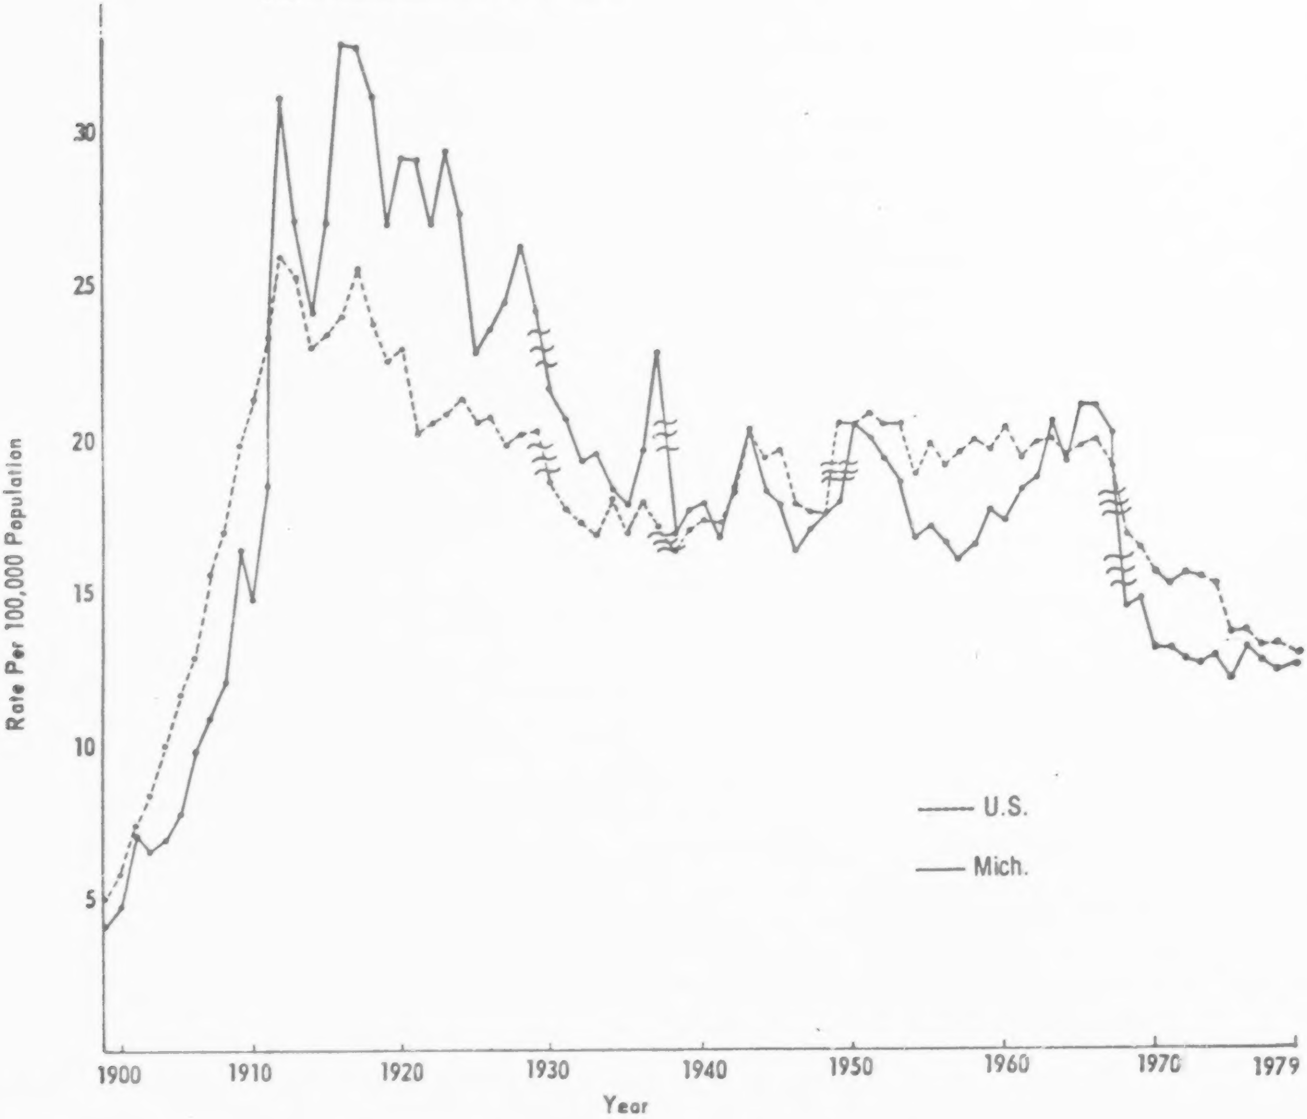
FIGURE 2.42 - Age-Specific Atherosclerosis Death Rates[1] by Race, Michigan Residents, 1979



---

[1] - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

FIGURE 2.43 - Atherosclerosis [1] Death Rates, Michigan and United States Residents, [2] 1900-1979.[3]



---

[1] Prior to 1979 termed Arteriosclerosis

[2] National rates are from death registration states for 1900-1932 and the United States for 1933-1979; U. S. rate for 1979 is provisional.

[3] Although Michigan and United States arteriosclerosis death rates are comparable for any given year, changes in the International Classification of Diseases over the years have made historic comparison of these rates extremely difficult. Comparability breaks are especially pronounced in the 1930, 1939, 1949 and 1968 revisions. Analysis of arteriosclerosis death rates over the time period 1900-1979 requires detailed study to maintain comparability.

[1] For years 1970-1978 the category was termed arteriosclerosis.

2 - Based on age-specific death rates per 100,000 population in specified group. Computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940; see Technical Notes.

3 - The introduction in 1979 of the 9th Revision of the International Classification of Diseases for coding causes of death resulted in substantial changes in this category, making trend comparrisons difficult. The estimated comparability ratio for this category is 1.0649. Note that comparability ratios were developed for comparing crude death rates, and they are not strictly applicable for comparing age-adjusted death rates. For further discussion of comparability ratios see Qualifications and Limitations of Data and Calculations.

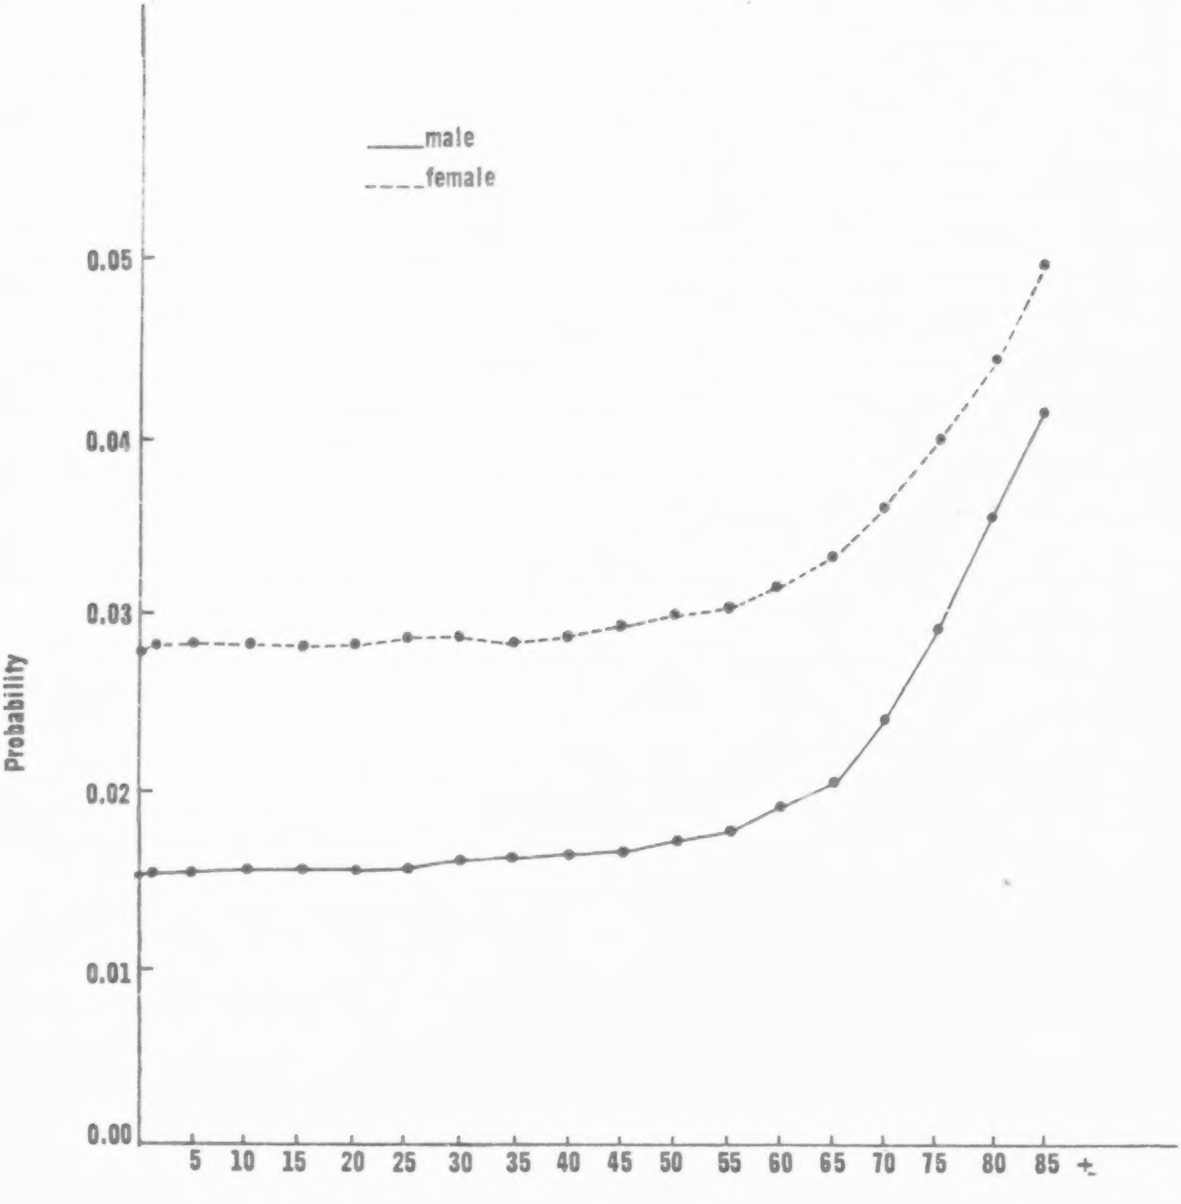
FIGURE 2.44 - Probability of Eventually Dying from Atherosclerosis[1] by Age and Sex, Michigan Residents, 1977-1979[2]



---

[1] This category was termed arteriosclerosis in 1977 and 1978.

[2] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

SUICIDE

There were a total of 1,143 suicide deaths in 1979, making suicide the 10th leading cause of death. Seventy-four percent of the deaths resulting from suicide were to males. About 88 percent of all suicide deaths were to white persons.

Fifty percent of all suicide deaths occurred at or below the age of 38. The median age of death for males was 37 years, 4 years below that for females. The median ages at death for white males and females were 38 and 43 years respectively. For other than white males the median age at death was 32 years and for other than white females, 36 years (Table 2.47).

The crude suicide death rate in 1979 was 12.4 per 100,000 population. The crude rate for males (18.7) was three times that for females (6.3). Age-specific rates for males were higher in all age groups (Table 2.48 and Figure 2.45). While suicide rates for males were highest among men in their twenties and those aged 65 or over, the rates for females were highest between ages 35 and 64 and declined in the older age groups. The suicide death rate for males 65 or over was nearly 7 times the comparable rate for females (34.7 deaths and 5.1 deaths per 100,000 population, respectively).

The crude suicide death rate for the white population was 18.7 percent higher than that for the other than white population. The age-adjusted rate for white persons was 10.3 percent higher than that for other than white persons. Age-specific rates by race from Table 2.48 are displayed in Figure 2.46. Age-specific rates for white and other than white persons were similar through age 44, beyond which age the rates for white persons were consistently higher. The suicide death rate for the other than white population aged 65 or over was 10.7, well below the comparable rate for white persons of 18.5. For males over age 64 the differential by race was even more pronounced. For white males over age 64 the suicide death rate was about double the comparable rate for other than white males (36.7 compared to 18.5).

The suicide death rates of Michigan and the United States followed a cyclical path from 1900 to 1944. There were two complete cycles of rising then falling rates in that

1 - Note that death rates are shown on a logarithmic scale: vertical distances represent relative differences in rate rather than absolute differences.

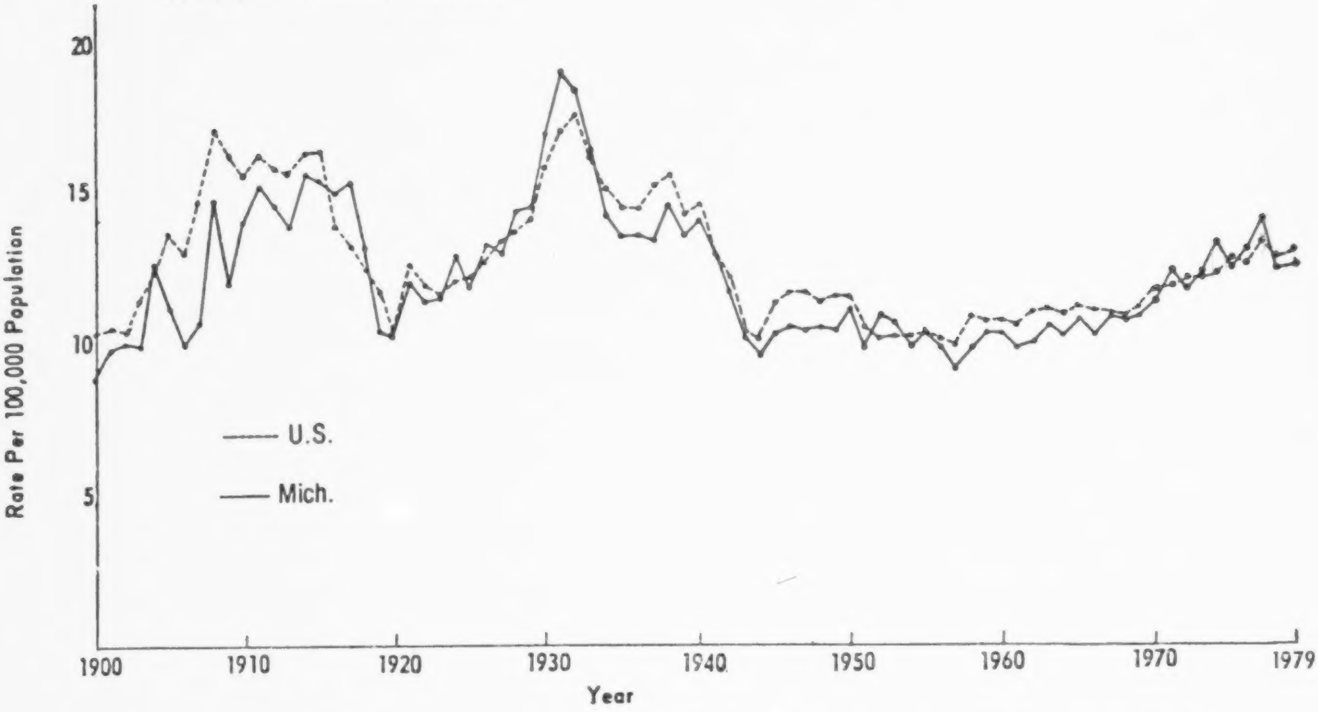
time period. The rates after 1944 held fairly stable for several years then began a slow increase in both Michigan and the United States. There is strong similarity in both the trend and magnitude of Michigan and national rates in this century (Figure 2.47). In 1900 the rate was 8.8 in Michigan, the lowest rate observed. The highest was 18.8 in 1931. For the nation high and low rates were observed in 1932 (17.4) and in 1944 and 1952 (10.0). In 1979 the provisional rate for the United States was 12.6, compared to Michigan's rate of 12.4.

Age-adjusted suicide death rates by race and sex for Michigan and the United States in the 1970's are presented in Table 2.49. Age-adjusted rates for suicide have increased for all major population groups in Michigan except white females. Although rates for other than white persons experienced a more substantial increase than those for white persons between 1970 and 1979, the rates for white persons remained higher than those of their other than white counterparts throughout the period. Rates for the nation were more stable. For white and other than white females the rates showed no clear trend, while there were relatively small increases for white and other than white males. The rates in Michigan for the other than white population were significantly higher than those of the nation. Rates in Michigan for the white population groups were slightly higher than those of the nation.

Suicides in Michigan were predominantly the result of one of four types of self-inflicted injury. Self-inflicted injury by firearms caused 601 deaths in 1979. Hanging, strangulation and suffocation resulted in 170 deaths. Self-inflicted poisoning by gases and vapors resulted in 157 deaths, of which 127 were attributed to motor vehicle exhaust gas and another 26 to other carbon monoxide poisoning. Combined with 105 deaths due to poisoning by drugs, medicaments, and biologicals, these four types of suicide accounted for 90.4 percent of all suicidal deaths to Michigan residents in 1979 (Table 2.50).

Using the Michigan mortality experience of 1977 through 1979, the chance of a male eventually dying from suicide is 0.016 at birth. The risk for females is 0.006. These probabilities hold relatively constant through age 20 then taper slowly with advancing age (Figure 2.48).

FIGURE 2.47—Suicide Death Rates, Michigan and United States Residents,[1] 1900-1979[2]



[1] National rates are from death registration states for 1900-1932 and the United States for 1933-1979; U. S. rate for 1979 is provisional.

[2] Suicide death rates since 1900 are suitable for general comparison over time but detailed study (such as time series) requires special consideration. See Technical Notes.

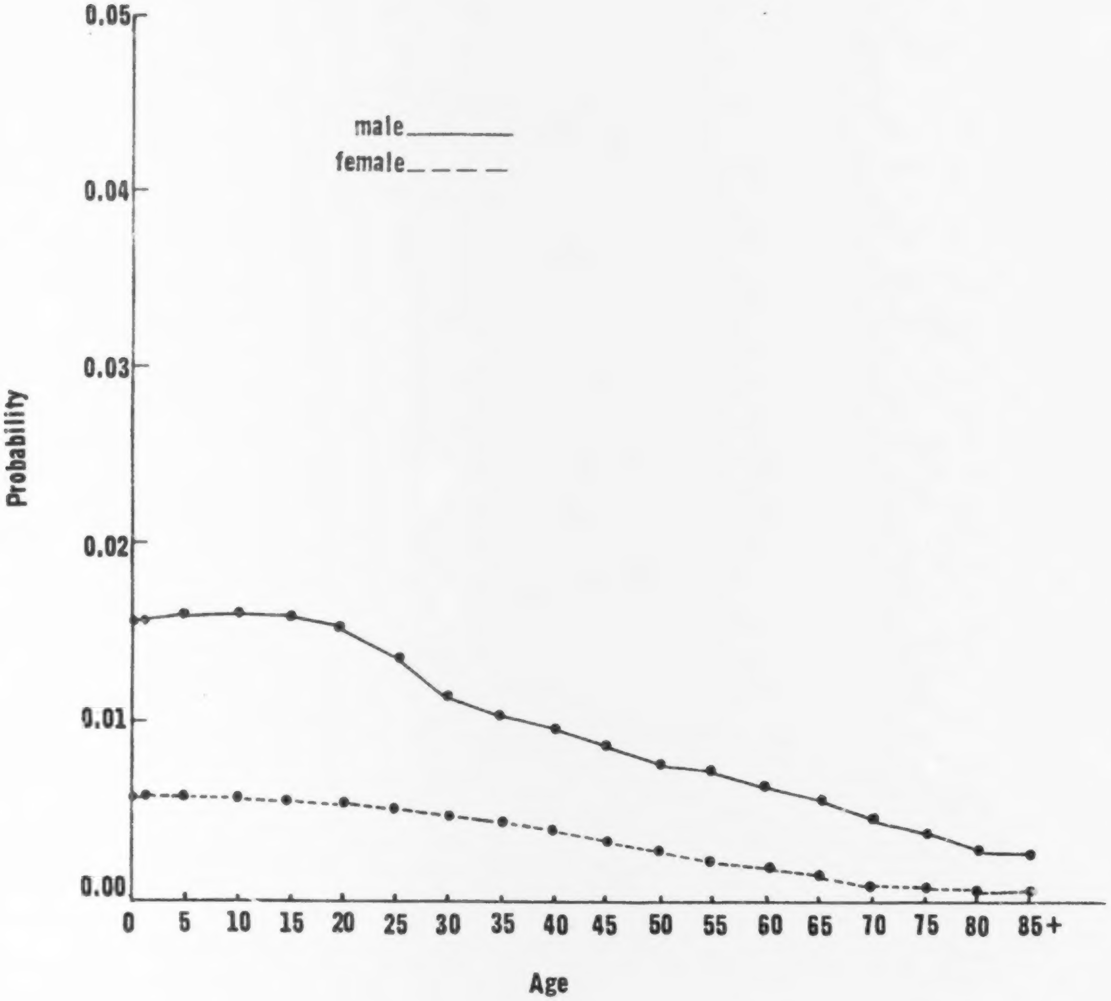
FIGURE 2.48 - Probability of Eventually Dying from Suicide by Age and Sex, Michigan Residents, 1977-1979[1]



---

[1] Note: Should comparisons be desired between this graph and a similar graph contained herein that pertains to some other specified cause of death, differences in scale may be encountered.

THE PROBABILITY OF EVENTUAL DEATH DUE TO A SPECIFIED CAUSE

While cause-specific death rates are useful in gauging the frequency of death due to certain causes and in making comparisons between areas or populations, they do not relate the risk that the condition imposes on the population with clarity. Mortality data can be used to develop this risk in probabilistic terms. Through the application of life expectancy techniques, a probability of death due to a given cause can be estimated. Such probabilities represent the average risk of eventual death being caused by a specified condition under an assumption that the mortality across all ages that was observed in a time period will remain unchanged through the remaining life of the population. These probabilities can be estimated for any given age attained. The following list relates the probability at birth of dying from the ten leading causes of death based upon Michigan mortality experience for the years 1977 through 1979.

DISEASE CATEGORY	PROBABILITY AT BIRTH OF EVENTUAL DEATH DUE TO CONDITION FOR:	
	Males	Females
Diseases of the Heart	.418	.439
Malignant Neoplasms	.203	.176
Cerebrovascular Diseases	.079	.125
Accidents and Adverse Effects	.047	.027
Chronic Obstructive Pulmonary Disease and Allied Conditions	.036	.014
Pneumonia and Influenza	.026	.028
Diabetes Mellitus	.016	.027
Chronic Liver Disease and Cirrhosis	.019	.010
Atherosclerosis	.015	.028
Suicide	.016	.006
All Other Causes	.125	.120
	1.000	1.000

The 1977 through 1979 data would indicate that 87.5 percent of all males and 88.0 percent of all females in Michigan will die from one of the ten leading causes if all things remain constant. Approximately four of every ten people will die from heart disease. Women face higher risks of death from heart disease, cerebrovascular disease, pneumonia and influenza, diabetes mellitus, and atherosclerosis than do males. At the same time, males are more likely to die from cancer, accidents, chronic obstructive pulmonary disease and allied conditions, chronic liver disease and cirrhosis, and suicide according to the mortality experience in Michigan during 1977 through 1979.

Related to the probability at birth of eventual death due to a given cause is the hypothetical gain in life expectancy that would result if a given cause of death were eliminated. Based on 1977-1979 mortality data, the average number of years of life gained by eliminating deaths due to a major cause is given in the list that follows. Deaths in infancy from all causes are added for comparative purposes.

DISEASE CATEGORY ELIMINATED	YEARS GAINED IN LIFE EXPECTANCY FOR:	
	Males	Females
Diseases of the Heart	4.88	3.34
Malignant Neoplasms	2.68	2.70
Cerebrovascular Diseases	0.62	0.82
Accidents and Adverse Effects	1.46	0.67
Chronic Obstructive Pulmonary Disease and Allied Conditions	0.34	0.17
Pneumonia and Influenza	0.23	0.19
Diabetes Mellitus	0.17	0.26
Chronic Liver Disease and Cirrhosis	0.36	0.22
Atherosclerosis	0.06	0.08
Suicide	0.46	0.19
All Causes of Infant Mortality	1.14	0.96

The largest gains in life expectancy would result from the elimination of heart disease and cancer, the two leading causes of death. Considering the number of deaths involved, relatively large gains in life expectancy would result from the elimination of infant mortality, accidents and suicide. Eliminating deaths in the younger age groups, where these causes are concentrated, has a greater impact on the potential number of years of life to be gained than eliminating deaths in the older age groups.

INFANT DEATHS

Of the 73,480 deaths occurring to Michigan residents in 1979, 1,921 occurred to individuals less than one year of age. The frequency of infant deaths in Michigan has declined by 42.8 percent since 1969 when there were 3,356 such deaths (Table 2.51). The number of infant deaths has declined steadily since 1957 with the single exception of 1970. The 1979 figure was 0.5 percent below the number for 1978. Nationally, the number of infant deaths in 1979 was 45,000 (provisional), 40.1 percent below the number in 1969 and 2.1 percent less than the final figure of 45,945 in 1978.

The rate of death for infants under the age of one year has dropped considerably since 1900. In that year there were 157.1 infant deaths for every 1,000 live births. This means that about 16 of every 100 infants did not survive their first year. This rate fell below 100 by 1914 (96.8), to less than 70 by 1927 (67.7), and to less than 50 by 1937 (47.8). During the 1940's the Michigan infant death rate declined from 40.6 in 1940 to 28.9 in 1949. Relative declines in rate slowed considerably in the 1950's and 1960's. It was not until 1971 that the rate dropped below 20 to 19.5. The rate of decline in the 1970's compares favorably with the rate of decline observed before 1950. In 1979, the Michigan infant mortality rate was 13.3 (Figure 2.49).

During the period 1915-1928, the rate for Michigan was above that for the United States 9 of 14 years. From 1929 through 1969, Michigan's infant death rate was consistently below the national statistic. From 1970 through 1975 the infant mortality rate in Michigan was slightly higher than the rate for the nation. Since 1976 the rates for the state and nation have been similar. The rate for the United States in 1979 was 13.0 (provisional).

Table 2.52 shows the numbers of infant deaths and infant death rates by age at death for the period 1970-1979. The number of infants that died during the first day of life in 1979 (754) is greater than the number of deaths of infants aged 1-11 months (626). About 67 percent of all infant deaths occurred within the first month

1976	1,978	15.06	829	6.31	402	3.06	193	1.47	554	4.22
1977	1.945	14.05	794	5.74	374	2.70	199	1.44	578	4.18
1978	1,931	13.91	717	5.17	384	2.77	180	1.30	650	4.68
1979	1,921	13.30	754	5.22	356	2.46	185	1.28	626	4.33

of life in 1979, with about 58 percent in the first week. These percentages were 77 and 71 percent in 1970. A review of Table 2.52 reveals that the 34.6 percent decline in the infant mortality rate since 1970 stems largely from reductions in the rate of death for those less than 7 days of age. The death rate for infants during their first day of life has declined 34.4 percent since 1970, while the death rate for ages 1 through 6 days has declined by 61.4 percent over the last nine years. In contrast, the death rate for infants aged 7 to 27 days actually increased in the mid-1970's before dropping in 1979 to about the 1970 level. Death rates for infants aged 28 to 364 days fell in 1976 and 1977 but increased in 1978 to about the same level as observed in 1970. The death rate for this age group in 1979 declined to 4.33, which is 8.1 percent lower than the comparable rate for 1970.

Infant mortality rates have varied considerably by race. Rates for white and other than white infants since 1950 are graphically displayed in Figure 2.50. Rates for other than white infants were higher throughout the period. Although the rates for both race groups have declined, those for white infants have decreased by a relatively larger amount. As a result, the racial differential in infant mortality rates has increased since 1950. Between 1950 and 1965, the infant mortality rate for white infants declined moderately while that for other than white infants remained relatively stable. Between 1965 and 1970 the rate for white infants declined by 14.7 percent while the rate for other than white infants declined by 20.5 percent. Since 1970, however, the rate for white infants has dropped by 38 percent while for other than white infants the decline was 26 percent. The rate for other than white infants of 35.6 in 1950[1] was 40 percent higher than that for white infants (25.4) whereas in 1979 the rate for other than white infants of 22.0 was 93 percent higher than that for white infants (11.4).

Michigan resident infant deaths in 1979 are listed by cause of death classification and age at death in Table 2.53. Congenital anomalies caused the death of 344

	Total	1,921	754	356	185	495	131

infants and was the specific disease category most frequently reported. Respiratory distress syndrome was responsible for 258 infant deaths in 1979, while sudden infant death syndrome was listed as the cause of 246 deaths. Over half (52.8 percent) of all infant deaths were attributed to conditions originating in the perinatal period. This proportion was 81.6 percent for deaths which occurred during the first day, 71.3 percent for deaths of infants at ages 1 through 6 days, and 54.1 percent for deaths of infants 1-3 weeks of age. In contrast, 37 of 495 deaths (7.5 percent) of infants from 1 to 5 months of age were caused by conditions originating in the perinatal period.

The most frequent causes of death during the first day were congenital anomalies (16.4 percent) and disorders relating to short gestation and unspecified low birthweight (16.3 percent). Respiratory distress syndrome caused 13.7 percent of the deaths under 1 day of age, and 30.3 percent of those to infants 1-6 days of age. The second most frequent cause of deaths to infants aged 1-6 days was congenital anomalies (22.5 percent). For infants who died at 1-3 weeks of age the most frequent causes were congenital anomalies (24.3 percent) and respiratory distress syndrome (16.8 percent). Sudden infant death syndrome was reported as the cause of 40.4 percent of the deaths to infants from 1 to 5 months of age. This cause was also the leading cause of death for infants from 6 to 11 months of age (22.1 percent). The 24 deaths due to accidents to infants aged 6-11 months represent 18.3 percent of the total deaths in this age group, while accidental deaths represent only 2.8 percent of all infant deaths.

Infant deaths and death rates by cause are shown for white and other than white infants in Table 2.54. The most frequent causes of death for white infants were congenital anomalies (289 deaths), sudden infant death syndrome (165 deaths), and respiratory distress syndrome (164 deaths). For other than white infants the order of these causes was reversed, with respiratory distress syndrome, sudden infant death syndrome, and congenital anomalies causing 92, 80, and 53 deaths respectively. While the death rate from all causes combined for other than white infants was 93 percent

[2] Rates per 100,000 live births

above that for white infants, the differential by race was 139 percent for deaths due to certain conditions originating in the perinatal period. Rates for other than white infants were 3 to 4 times those for white infants for deaths due to meningitis, pneumonia and influenza, disorders relating to short gestation and unspecified low birthweight, and for deaths in the categories of newborn affected by maternal complications of pregnancy and all other and ill-defined conditions originating in the perinatal period. The death rates for respiratory distress syndrome and sudden infant death syndrome for other than white infants were 2.6 and 2.3 times, respectively, the comparable rates for white infants. Cause-specific infant death rates for white infants were higher for congenital anomalies and for the category newborn affected by complications of placenta, cord, and membranes.

The infant death rate from all causes for males was 28 percent greater than that for females. This was also the differential for deaths due to certain conditions originating in the perinatal period. The death rate of 33.7 for males for certain gastrointestinal diseases and other infectious and parasitic diseases was 2.4 times the rate of 14.2 for females. The rates for males were from 1.5 to 1.7 times those for females for deaths due to birth trauma, respiratory distress syndrome, other respiratory conditions of newborn, infections specific to the perinatal period, and sudden infant death syndrome. Death rates for accidents and homicide were similar for males and females. The only cause for which the rate was higher for females was neonatal hemorrhage (Table 2.55).

[2] Rates per 100,000 live births

Infant mortality rates by race are presented in Table 2.56. These data are from a file of merged live birth and infant death information. The rates presented are for Michigan residents born in 1978. Note that this matched file is approximately 97.3 percent complete and, therefore, the rates presented are understated. The rates for black infants (24.2) and American Indian infants(23.9) were more than twice that for white infants (11.3). The rate for infants of other races (7.0) was well below the rate for all infants. The death rate for infants aged less than seven days showed similar variations by race (Table 2.57).

Table 2.56 - Infant Deaths, Live Births, and Infant Death Rates by Race, Michigan Resident Infants Born in 1978

[1] Deaths to infants less than seven days old.

[2] Per 1,000 live births.

Data from the matched file on infant mortality rates by age of mother and race of child are presented in Table 2.58. Infant death rates display a parabolic relationship with mother's age. The rates are highest for infants born to mothers under age 20. The infant mortality rates of 20.3 and 19.8 for mothers under 15 years old and 15-19 years old respectively are nearly double the rate of 10.3 for mothers aged 25-29 years. The infant mortality rate for mothers 40 or over is about 25 percent higher than that for mothers of all ages combined.

Rates for white and other than white infants generally follow the pattern of association to mother's age, but infant mortality rates for the other than white group are significantly above those for the white group. For babies born in 1978, the rate for other than white infants was more than twice as high as that for white infants. The rate for other than white infants was higher in each age group. The smallest differential was for mothers under age 20 where the rate for other than white infants was one and a half times that of white infants.

Table 2.59 displays the variation in infant death rates according to the number of the mother's prenatal visits. The infant death rate for mothers who had no prenatal care was 64.1, over ten times as high as the low rate of 6.2 for mothers who had 15 to 19 prenatal visits. The rate associated with mothers who had 1-4 visits was 9.2 times the low rate, while the rate associated with mothers who had 5-9 visits was nearly 3 times as high as the low rate. The infant death rate for mothers with 20 or more prenatal visits was 17.7 percent higher than the low rate, reflecting the likelihood that a high number of prenatal visits is connected with a problem pregnancy.

Mothers with fewer than ten prenatal visits had 31.3 percent of all live births but 57.9 percent of all infant deaths. Mothers who had ten or more prenatal visits had 65.3 percent of live births and 32.7 percent of infant deaths. The infant death rate for mothers who had fewer than ten prenatal visits was 24.8. This is 3.7 times the rate of 6.7 for mothers who had ten or more prenatal visits.

[1] Race not stated included in total columns only

The differential in mortality rates between other than white and white infants noted above is significantly altered when comparisons are made within the same range of prenatal visits. While the overall rate for other than white infants was 108 percent higher than that for white infants, for mothers who had 1-4 and 5-9 prenatal visits the rates for other than white infants were 11.2 percent and 21.5 percent higher, respectively, than the comparable rates for white infants. For mothers with fewer than ten prenatal visits, the infant mortality rate for white infants was 22.3 and that for other than white infants 32.2. For mothers with ten or more prenatal visits, the rate for white infants was 6.0 and for other than white infants 11.8. The rate for other than white infants was 44.4 percent higher where the mother had fewer than ten prenatal visits and 96.7 percent higher where the mother had ten or more visits. Both of these racial differentials were less than the overall racial differential of 108 percent. This seemingly paradoxical result is explained by the differing distributions of the white and the other than white births. The overall infant mortality rate for each race is a weighted sum of the infant mortality rates for the different prenatal care categories. The weight for each prenatal care category is the ratio of the number of live births in that category to the total number of live births. Since a greater proportion of the other than white live births are to mothers in the categories with fewer prenatal visits, the higher infant mortality rates in the categories with fewer prenatal visits are more heavily weighted for the other than white population.

When deaths under one week are grouped together with fetal deaths the resultant total is called perinatal deaths. By placing a ceiling of six days for the infant component of perinatal deaths, most accidental and environmental causes of death are eliminated. In 1979, Michigan resident perinatal deaths numbered 2,326 and the perinatal death rate was 16.0. This rate was 16.6 in 1978 and 26.0 in 1970.

As with infant death rates, perinatal mortality rates vary considerably with race, age of mother, and number of prenatal visits. Tables 2.60 and 2.61 show perinatal deaths and rates by age of mother, the number of the mother's prenatal visits, and the race of the fetus or infant for fetal deaths and live births occurring in 1978. As with Tables 2.58 and 2.59 a part of the data, i.e., hebdomadal deaths, are drawn from a merged file of birth and death data. As a result, perinatal deaths and rates are slightly understated. Table 2.60 makes clear the increased risk of death to fetuses and infants of mothers under 20 or age 40 or greater. Minimum risk in 1978 was associated with mothers 25-29 years of age. Table 2.61 indicates that the risk of perinatal death is more than eleven times as great for fetuses and infants whose mothers had fewer than five prenatal visits compared with mothers with ten or more visits. The risk associated with 5-9 prenatal visits is 3.4 times as great as for the lowest risk category (10-14 visits).

The overall perinatal mortality rate for other than white fetuses and infants was nearly twice as high as for whites. The highest perinatal mortality rate for both whites and other than whites was associated with mothers 40 years or over. While for whites the minimum risk was clearly associated with mothers 25-29 years of age, there was little difference by age of mother in the rates for black fetuses and infants born to mothers from 15-39 years of age (Table 2.60).

For both white and other than white fetuses and infants the highest mortality rates were associated with mothers who received less than 5 prenatal visits. Where the mother received no prenatal care the rate for other than whites was 2.3 times the comparable rate for whites. However, for fetuses and infants born to mothers who received 1-4 prenatal visits the rates were similar for whites and other than whites. The differentials by race were also considerably less than the overall differential for fetuses and infants born to mothers who received 5-9, 15-19, or 20 or more visits (Table 2.61).

The median birth weight of infants born in 1978 and dying prior to 1 year of age was 1,758 grams (Table 2.62). The median birth weight of all Michigan resident

Median Weight in Grams	1,758	1,793	1,786	1,701	1,700	1,985	1,928	255

live births in 1978 was 3,374 grams. For all maternal age groups, the median birth weight for infant deaths was below what is considered a normal weight range.

Infant death rates by race, birthweight and age at death are displayed in Table 2.63 for infants born in 1978. While the overall infant death rate for other than white infants was more than double that of white infants, the rates for white and other than white infants were quite similar for the low birthweight categories. For infants weighing 2,501 grams or more the rate for other than white infants exceeded by 53 percent that for white infants. A large part of the difference between infant death rates for white and other than white infants is due to the fact that a greater proportion of the other than white infants were born at weights below 2,501 grams (13.2 percent for other than white infants compared to 5.9 percent for white infants).

The differentials in infant death rates by race for deaths under 28 days and from 28-364 days were similar to that for all infant deaths. In each of the age groups the differentials in infant death rates by race in the different birthweight categories were less than the overall differential. For infants weighing less than 1,501 grams and for those from 1,501-2,500 grams the rates for deaths before 28 days were greater for white infants than for other than white infants (4.4 percent and 54.2 percent respectively). However, this relationship was reversed for deaths from 28-364 days for the same birthweight categories. For deaths of these older infants the rates for other than white infants exceeded those for white infants by 106.9 percent and 71.3 percent respectively for infants weighing less than 1,501 grams and for those weighing 1,501-2,500 grams. It is interesting to note that although the death rates for white infants under 28 days of age were greater than for other than white infants in both of the low weight categories examined, the rate for all low weight infants who died before 28 days was greater for other than white infants (94.7 compared to 93.7). This is the result of a greater proportion of other than white infants being born at weights under 1,501 grams where the infant death rates are much higher.

COMMUNICABLE DISEASE DEATHS

Although comprising a smaller proportion of deaths than they have in the past, communicable disease deaths continue to be a major concern. In 1979, deaths from all infectious and parasitic diseases numbered 553. As can be observed from Table 2.64, over half of these deaths were caused by septicemia (300 deaths). Tuberculosis and viral hepatitis caused 62 and 26 deaths respectively. When death attributed to late effects of tuberculosis are included, the number of deaths from tuberculosis rises to 76.

The distribution of infectious and parasitic disease deaths by age, race, and sex for 1979 is given in Table 2.65, and the corresponding death rates are shown in Table 2.66. Note that infants accounted for 4.9 percent of all infectious and parasitic disease deaths while comprising 2.6 percent of all deaths and that other than white persons accounted for 23.5 percent of all infectious and parasitic disease deaths but only 12.8 percent of deaths from all causes. The death rates were highest for persons aged 65 years and over (35.4 deaths per 100,000 population) and for infants under 1 year (19.8). Rates for males were somewhat higher than for females, and rates for other than white persons were about double those for white persons.

Deaths due to such diseases as diptheria, scarlet fever, streptococcal sore throat, small pox, typhoid fever, measles, poliomyelitus and others have been virtually eliminated not only in Michigan, but across the nation. Table 4.7 illustrates trends in deaths from the major communicable diseases.

INJURY AT WORK

There were 217 deaths reported as resulting from injuries at work in 1979, 39 fewer than in the previous year. These include all cases in which the underlying cause of death was external and the injury was reported to have occurred at work, whether or not the injury was work-related. Table 2.67 gives the frequency of deaths due to injuries at work by place of occurrence. The most common site was an industrial place or premises, with 67 deaths. Second in frequency were injuries taking

TOTAL	217

places on streets and highways (51 deaths). There were also 36 deaths from injuries at work occurring in public buildings and 16 from injuries taking place on farms.

The most frequent cause of death associated with injuries at work was motor vehicle traffic accidents, involving 43 deaths or 19.8 percent of all such deaths (Table 2.68). The second most common cause was homicide and legal intervention, accounting for 36 deaths and 16.6 percent of the total. Accidents caused by machinery resulted in 26 deaths, while accidental falls and being struck accidentally by a falling object accounted for 24 and 16 deaths respectively. Accidents caused by an electric current accounted for 11 injury at work deaths, while motor vehicle nontraffic accidents were the cause of an additional 11 deaths. There were also 8 suicide deaths which occurred at work, as well as 8 deaths caused by injuries at work involving air and space transport accidents.

LIFE EXPECTANCY

The life expectancy of a Michigan resident at birth is 73.3 years, based on 1979 mortality data and population estimates. Males demonstrated a significantly shorter longevity than females. In 1979 the years remaining at birth are 70.0 for males and 76.8 for females. This results from the higher mortality rates of males at all ages.

Life expectancies by sex in selected years for Michigan and United States residents are presented in Table 2.69. It can be seen that longevity has increased greatly in Michigan since 1901, by 16.6 years for males and by 21.7 years for females. Females born in Michigan in 1901 could expect to live 1.7 years longer than their male counterparts. By 1950 the differential in life expectancy between the sexes was 5.5 years. This disparity increased to 7.6 years by 1971, remained constant through 1973, and by 1979 had declined to 6.8 years. Between 1971 and 1979 life expectancy for males increased by 2.7 years while for females the increase was 1.9 years.

The life expectancy of Michigan residents was well above that for the nation in 1901, but this differential had virtually disappeared by 1950. In 1978 the

----	----	1979	70.0	76.8

1 - Michigan data for years 1920, 1930, and 1940 are for white persons only.

the life expectancy of males in Michigan was slightly above that for males nationwide, 69.6 years compared to 69.5 years, while longevity for females residing in this state was 0.8 years below the average for the country. Note that females have consistently demonstrated greater longevity than males both in Michigan and the United States.

White persons displayed a life expectancy 5.0 years greater than other than white persons in 1979. The life expectancy of white males was 5.3 years greater than that of males of other races in 1979 compared to a differential of 5.8 years in 1950 (Table 2.70). In 1970 the differential was 7.2 years, due in part to an actual reduction in life expectancy for other than white males between 1960 and 1970. Since 1970 life expectancy for other than white males has increased 7.2 percent, from 61.0 to 65.4 years. This is a reflection of the recent decline in mortality rates for several leading causes of death for this group. The change in the differentials by race for female expectancies has been much more pronounced. In 1950, Michigan resident white females had an average longevity 8.5 years greater than females of all other races. This disparity declined to 4.6 years in 1979.

The expected number of years of life remaining are presented graphically by age, race, and sex in Figure 2.51. The number of years of life remaining for females is greater than that for males throughout life. At age 60 the differential is 4.6 years for white males and white females, and 3.[illegible] years for other than white males and females. Other than white persons display slightly greater life expectancies in the older age intervals than their white counterparts. The average number of years remaining for other than white females surpasses that of white females between ages 75 and 80. Other than white males display a greater expectation than that of white males at ages 60 and over.

PLACE OF OCCURRENCE

There were 2,051 Michigan resident deaths in 1979 that occurred outside the state. This represents 2.8 percent of all resident deaths. 459 Michigan resident deaths occurred in the state of Florida in 1979. This is 22.4 percent of all resident

out-of-state deaths, more than in any other area. The border areas of Indiana, Ohio, Wisconsin, and Canada accounted for 42.1 percent of all resident deaths outside Michigan. In addition to the above-mentioned areas, over 50 Michigan resident deaths also occurred in each of the following states: Minnesota, Arizona, Illinois, Texas, and California. Michigan resident deaths occurred in all but four of the 50 states in 1979 (Table 2.71).

Of the non-residents that died in Michigan in 1979, 44.9 percent were from the border areas, 16.4 percent were Floridians and 9.8 percent were from Illinois. Overall, non-residents who died in Michigan represented 42 states and several foreign countries.

[1] Number of persons married or divorced per 1,000 population

BEST AVAILABLE COPY

The number of marriages and divorces occurring in Michigan has increased considerably since 1900. While the frequency of marriage has generally followed the growth of Michigan's population, the rate of persons dissolving their marriages has increased nearly fourfold since 1900. The smallest number of marriages in the years 1900 to 1979 was 23,295 in 1900, while the largest number was 94,486 in 1973. After steep declines in the number of marriages in 1974 and 1975, and a smaller decline in 1976, the number of marriages has increased during each of the past three years. The number of marriages recorded in 1979 was 89,450, an increase of 1.3 percent over the 1978 figure. The number of divorces and annulments has increased from a low of 2,435 in 1900 to a high of 45,029 in 1978. For 1979 there were 44,242 divorces and annulments reported, a decline of 1.7 percent from the figure for 1978.

MARRIAGES

Since 1900, there have been noticeable changes in the marriage rates both nationally and in Michigan (Figure 3.1). The marriage rates observed for the state have generally followed the pattern of rising and falling rates observed nationally. Strong historic shifts in rates have been related most notably to the factors of war and the economy. The highest rates observed during this century were for the years immediately following the end of the two World Wars (27.7 in 1919 and 27.6 in 1946). The lowest rates occurred during the Great Depression of the 1930's. The number of persons married each year per 1,000 population was higher in Michigan than in the country for 19 of the 26 years from 1900 through 1925. Since 1926, Michigan's marriage rate has been lower than that of the nation, excepting only the years 1964 through 1969. The marriage rate for Michigan in 1979 was 19.4, up slightly from the 1978 rate of 19.2 (Table 3.1). The provisional rate for the nation in 1979 was 21.5, 10.8 percent above that of Michigan.

Residence of Couples Marrying in Michigan

When presenting statistics of births, deaths and fetal deaths it is possible to provide total resident figures due to an interstate agreement for exchange of nonresident event information. Thus, should a Michigan resident give birth in some other state, the state will forward the information to Michigan. No such agreement exists for marriages.

FIGURE 3.1 - Marriage Rates, Michigan and United States[1] Occurrences, 1900-1979

---

[1] Number of persons married per 1,000 population

[2] Beginning with 1978, marriage data for the United States include nonlicensed marriages registered in California. If nonlicensed marriages were included in the 1977 total, the marriage rate would increase from 20.1 to 20.4

This is an important consideration when analyzing marriage statistics. The marriage data presented are drawn from all marriages performed in the state regardless of the couples' residence.

Table 3.2 indicates that, in general, most of the couples marrying in Michigan are residents of the state. For marriages occurring in Michigan 97.3 percent of the brides were residents of Michigan, while 94.8 percent of the grooms were residents of the state. These figures are somewhat higher than those for marriages occurring in Michigan in 1970. Over the decade the proportion of marriages where both the bride and groom are not residents has declined substantially. These data indicate that the general characteristics of marriages occurring in Michigan should be representative of marriage patterns for Michigan residents.

There were a total of 2,382 non-resident brides married in Michigan in 1979. The figure for grooms is almost double that of brides, numbering 4,631. Table 3.3 shows the most frequent residences of non-resident brides and grooms married in Michigan. The nearby states of Illinois, Indiana, Ohio and Wisconsin are the states of residence for 43 percent of all non-resident grooms and 53 percent of non-resident brides.

Month of Marriage

The number of marriages occurring in Michigan varies with the seasons. The most popular month for marriages in 1979 was June, with 13.1 percent of all marriage ceremonies being performed during this month. August and September were also popular choices, with 12.2 and 10.8 percent respectively of all marriages. Fewer marriages occurred during the winter months. The lowest figure was for January, with slightly less than one third the number which occurred in June (Table 3.4)

Age at Marriage

Examination of the data in Table 3.5 reveals that females generally marry at a younger age than do males. The number of females who marry before the age of 20 is two and a half times the corresponding frequency for males. Between ages 20 and 24 the numbers of brides and grooms are similar. Among persons 25 and over, males marry more frequently than females. In 1979 the median age of brides marrying in Michigan was 23 years, while the 50th percentile for grooms was 25.

[1] Number of persons married per 1,000 population
[2] 15-19 Population used to obtain rate

Since 1970, there have been significant declines in the marriage rates for both sexes under the age of 25 years. The largest decline observed is for males under the age of 20 years for who the marriage rate has dipped 57 percent. For persons between the ages of 25 and 44 the rates of marriage have increased since 1970 for both sexes, while rates for persons 45 and over have dropped slightly.

The distribution of marriages by the age of bride and groom is shown in Table 3.6. The data in Tables 3.7 and 3.8 indicate that there has been a rise in the age at first marriage, and a trend toward a younger age for remarriages among both males and females. Between 1970 and 1979 the median age at first marriage increased from 20 to 21 for brides and from 21 to 23 for grooms. In the same period the median age at remarriage dropped from 33 to 31 for brides and from 36 to 35 for grooms. The most frequent age group for first marriage was 20-24 for males in both 1970 and 1979. Among females, the modal age group in 1970 was under 20 years. For brides, data for 1979 indicate a shift in mode to the 20-24 year age group for first marriages. The most frequent age interval for remarriage among males was 45 years of age or older in 1970 and 35-44 years of age in 1979. For females the most frequent age of remarriage shifted from the 45 and over age group in 1970 to the 25-29 age group in 1979.

Remarriages

These changes in age at remarriage are associated with increases in the frequency of second and higher order marriages. In 1970, the percent of all marriages that were remarriages was 23.4 for brides and 24.2 for grooms. In 1979 comparable percents were 31.5 for brides and 33.6 for grooms. This change in the proportion of all marriages which are remarriages is displayed graphically in Figure 3.2. Between 1960 and 1965, the proportion of remarriages dropped. Since 1965, this proportion has increased. The increase in the period 1972 through 1975 was especially marked for both sexes.

As remarriages can only occur when a prior marriage has been terminated by divorce, annulment or death of a spouse, it is apparent that persons remarrying will be generally older. Tables 3.9 and 3.10 demonstrate that the order of marriage has a strong positive relationship with the age of both brides and grooms. Note, however, the downward shift

between 1970 and 1979 in the age distribution for third and higher order marriages. The median age at marriage declined by three years during this period for third marriages and fourth and higher order marriages for both brides and grooms.

The frequency of remarriages among females increased by 30.6 percent between 1970 and 1979, while the number of brides who had been married at least three times previously increased by 43.2 percent. The increases for males were even more dramatic. Total remarriages increased by 35.2 percent and fourth or higher order marriages increased in frequency by 77.2 percent during the decade.

Changes in the frequency of remarriages have varied substantially in different age groups. Among persons under age 25 of both sexes the number of remarriages declined, with the largest relative declines occurring among those under age 20. The number of brides between ages 25 and 29 who had previously been married increased by 69.0 percent between 1970 and 1979, while that of grooms increased 42.3 percent. The largest relative increase in numbers of remarriages for males and females occurred in the age group 30-34 years (97.7 percent for males and 97.3 percent for females). Numbers of remarriages also increased substantially for persons 35-44 years of age. For females 45 and over the number of remarriages declined, while for males the frequency increased.

First Marriages

First marriages are an interesting component of all marriages in that they constitute an event that can never be duplicated. The frequency of first marriages can not be directly affected by rates of divorce or deaths to married persons and as such reflect the propensity of the population as a whole to enter into marital agreements.

There has been a general decline in both the number and rate of first marriages between 1970 and 1979. The number of first marriages dropped 12.9 percent for women and 14.8 percent for men. The rate of first marriages dropped 15.5 percent for women and 18.1 percent for men. This downward trend in the number and rate of first marriages has not been consistent, however. For men and women, the number and rate of first marriages remained fairly constant between 1970 and 1972, dropped between 1972 and 1976, and increased between 1976 and 1979 (Tables 3.11, 3.12, 3.13 and 3.14).

[1] Number of persons married per 1,000 population

[2] Grooms under 15 included in age 15-19

Changes in the frequency of first marriages have varied in different age groups. The greatest decline in first marriages occurred in the under 20 age group for both brides and grooms, and the decline has been consistent over the period 1972-1979. The number of first marriages in the under 20 age group dropped by 41.5 percent for brides and 53.1 percent for grooms between 1970 and 1979 while the corresponding rate for first marriages dropped 45.2 percent for brides and 56.5 percent for grooms. The number and rate of first marriages also declined subtantially for grooms in the 20-24 age group. There were significant increases in the number and rate of first marriages of brides and grooms between ages 25 and 34. Since 1970 the number of first marriages has declined for persons aged 40 or over. The increase in the overall rate of first marriages between 1976 and 1979 is due to a rise in the rates of first marriages for brides aged 20 through 34 and grooms aged 25 through 34. This is consistent with the general trend since 1970 for 25-29 year old brides and grooms but a shift in trend for the other age intervals.

Age at First Marriage

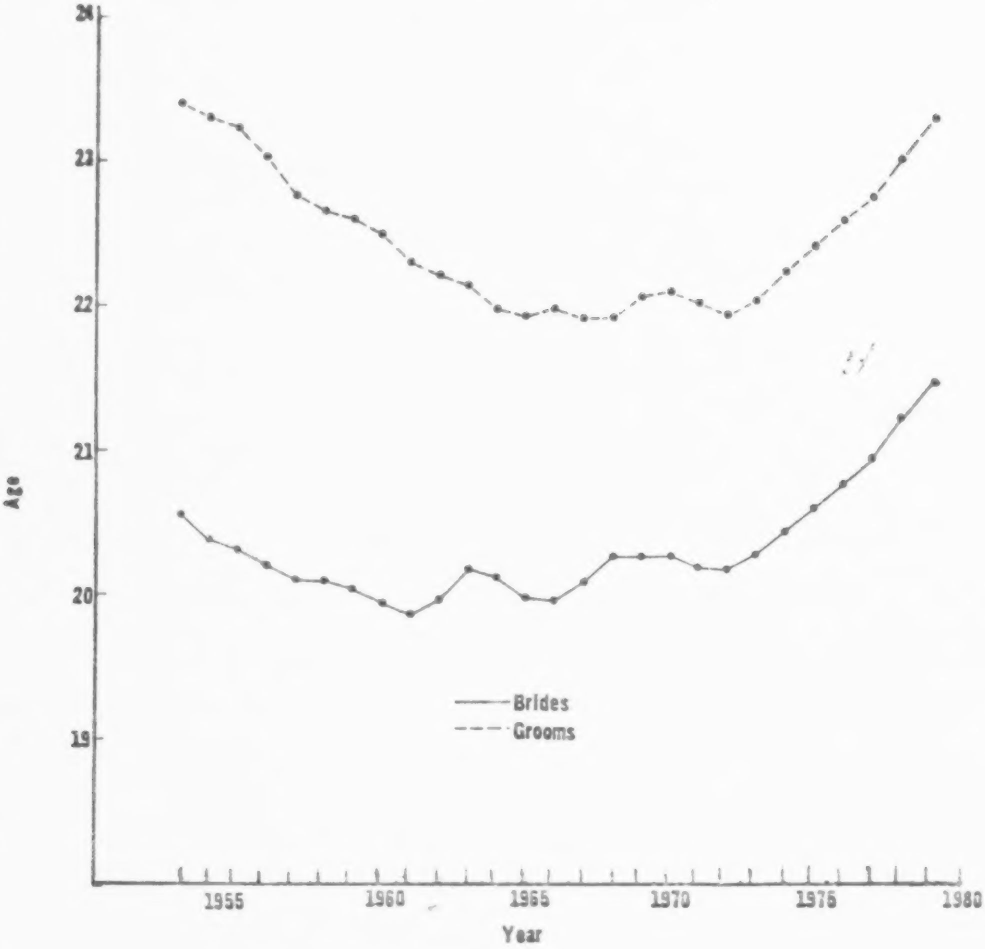
Age at first marriage declined for both brides and grooms between 1953 and the mid-1960's. This decline was greater for males than for females. Grooms were 34 months older than brides at the median in 1953, 23 months older in 1963 and 20 months older in 1968. During the past dozen years, the median age at first marriage has increased by a similar amount for both males and females. Grooms were 21 months older than brides at the median in 1979.

The median age at first marriage in 1979 was 21 years 5 months for brides and 23 years 2 months for grooms. The 1979 figure was the highest median age at first marriage recorded for brides during the period. The grooms' median age in 1979 was below the median observed during the years 1953-1954 but higher than those recorded in the past 23 years (Figure 3.3).

Divorces and Annulments

The number of reported divorces and annulments fell from 45,029 in 1978 to 44,242 in 1979. This constitutes a decline of 1.7 percent and represents only the second decline since 1963. The other decline occurred in 1977 (0.2 percent). In 1978 the number of

FIGURE 3.3 Median Age at first Marriage by Sex,
Michigan Occurrences , 1953-1979.



divorces and annulments increased by 4.6 percent. The number of divorces occurring nationally increased by an estimated 3.5 percent in 1979, the seventeenth successive year in which this figure has increased. In both Michigan and the United States the number of divorces in 1979 was more than two and one-half times the figure for 1960 (Table 3.15).

The number of persons divorced in Michigan per thousand population decreased from 9.8 in 1978 to 9.6 in 1979, while the national rate increased from 10.4 to 10.6. Michigan's divorce rate was higher than that for the United States each year from 1900 through 1947. In the following 32 years the Michigan divorce rate has been at or below the national rate 25 times. The lowest rate in this century for Michigan was 2.0 in the years 1900 and 1901 while the lowest national rate was 1.5 in 1900 and 1902. Since 1900 the divorce rates for only two years, 1946 (10.2) and 1978 (9.8) were higher than that for 1979 (Table 3.15 and Figure 3.4). The provisional United States estimate for 1979 was the highest national rate for the 80 years examined.

The number of children under 18 of couples dissolving marriages in 1979 was at least 47,019 (Table 3.16). This is a 21.6 percent increase since 1969. The number of children affected by divorce has steadily increased as a proportion of all children. This ratio increased from 6.5 per 1,000 Michigan children in 1960 to 12.6 in 1970 and 17.2 in 1979 (Table 3.17). The average number of children per divorce has, nonetheless, dropped slightly from 1.4 children in 1970 to 1.1 in 1979. The decline primarily reflects a decline in the proportion of divorces involving three or more children. It should be noted that Michigan live birth data indicate that there has been a decline in the relative proportion of women having third or higher order live births over the past decade. Data for the United States indicate a similar pattern.

1 - 1900-1942: United States Bureau of Census April 1 Census counts and July 1 estimates.
1943-1944: United States Bureau of Census November 1, 1943 estimate.
1945-1960: United States Bureau of Census April 1 Census counts and July 1 estimates.
1961-1964: University of Michigan Population Studies Center July 1 estimates.
1965-1969: Michigan Center for Health Statistics July 1 estimate.
1970: United States Bureau of Census April 1 Census counts.
1971-1979: United States Bureau of Census Priovisional July 1 estimates.

2 - For years prior to 1950 deaths under 1 month of age are included in deaths under 28 days.

3 - Estimate.

TABLE 4.2
LIVE BIRTH RATES, DEATH RATES (ALL AGES, INFANT, NEONATAL, PERINATAL, AND MATERNAL), FETAL DEATH RATIOS, MARRIAGE AND DIVORCE RATES MICHIGAN RESIDENTS, 1900-1979

(Birth rate, death rate for all ages, rate of persons married and rate of persons divorced per 1,000 population. Fetal death ratio, mortality rates for deaths under 1 year, under 28 days, and from 28-364 days per 1,000 live births. Maternal mortality rates per 10,000 live births. Perinatal mortality rate is number of deaths under 1 week and fetal deaths per 1,000 live births and fetal deaths.)

Year	Live Births	DEATHS							PERSONS	
		All Ages	Under 1 Year	Under 28 Days[1]	28-364 Days	Peri-natal	Fetal	Maternal	Married	Divorced

[1] Total live births for the years 1920 through 1959 differ from figures in Table 4.1 as they are derived from outside sources. Live births by age of mother were not tabulated in Michigan prior to 1960. These data were obtained from the following sources:

YEAR	SOURCE
1920-1923	Unpublished Tables from the National Center for Health Statistics
1924-1932	Bureau of the Census publication, *Birth, Stillbirth and Infant Mortality Statistics for Birth Registration Areas of the United States*
1933-1936	Unpublished Tables from the National Center for Health Statistics
1937-1949	Bureau of the Census publication, *Vital Statistics of the United States* series.
1950-1959	Department of Health Education and Welfare publication, *Vital Statistics of the United States* series.

TABLE 4.4

LIVE BIRTH RATES BY FIVE YEAR AGE GROUPS OF MOTHER
MICHIGAN RESIDENTS, 1920-1979

(Live Birth Rates are per 1,000 women per year. Total Fertility Rate is total children to 1,000 women in their lifetime assuming constant Live Birth Rates.)

YEAR	AGE OF MOTHER								TOTAL FERTILITY RATE
	10-14	15-19	20-24	25-29	30-34	35-39	40-44	45+[1]

[1] Meningococcal infections—Prior to 1952 data were for meningococcic meningitis. Tuberculosis, syphilis, gonorrhea and chancroid are resident cases.
[2] Effective January 1975 a new diagnostic classification system for tuberculosis was adopted. As a result, case counts and rates prior to 1975 are not directly comparable to the figures in 1975 and later years.

[1] From 1901 through 1920, syphilis includes all other venereal diseases; beginning with 1968 excludes aortic aneurysms not specified as syphilitic.
[2] Effective January 1975, a new diagnostic classification system for tuberculosis was adopted. As a result, deaths and rates prior to 1975 are not directly comparable to the figures in 1975 and later years.

TABLE 4.8
NUMBER OF DEATHS AND DEATH RATES BY SPECIFIED CAUSES
MICHIGAN RESIDENTS, 1900-1979
(Rates per 100,000 Population)

Year	Heart Disease[1]		Cancer (all forms)[2]		Cerebrovascular Disease[3]		Accidents (all forms)[4]		Motor Vehicle Accidents[5]		Diabetes		Pneumonia		Chronic Liver Disease and Cirrhosis[6]		Atherosclerosis[7]

1 - [illegible] of these were serum hepatitis.

2 - Effective January, 1975, a new diagnostic classification system for tuberculosis was adopted. As a result, direct comparison of case counts and rates between 1975 and preceding years will not be possible.

3 - Includes:

Meningitis, Aseptic	592	Staphylococcal Infections	96	Malaria	12	Diarrhea Epidemic Infants (under 1 year)	1
Meningitis, Excluding Aseptic	169	Encephalitis Infections	55	Rocky Mountain Spotty Fever	3	Leprosy	1
Ringworm	156	Typhoid Fever	14	Psittacosis	3	Tetanus	1
Meningitis, Influenzal	148	Dysentery Amebic	13	Congenital Rubella	3		

TABLE 4.16

NUMBER OF DEATHS BY CAUSE
MICHIGAN RESIDENTS, 1979

ICD LIST NUMBER	CAUSE OF DEATH	NUMBER
I.	INFECTIOUS AND PARASITIC DISEASES (001-139)	
003	Other salmonella infections	1
008	Intestinal infections due to other organisms	6
009	Ill-defined intestinal infections	9
011	Pulmonary tuberculosis	47
013	Tuberculosis of meninges and central nervous system	2
015	Tuberculosis of bones and joints	1
017	Tuberculosis of other organs	1
018	Miliary tuberculosis	11
027	Other zoonotic bacterial diseases	2
035	Erysipelas	1
036	Meningococcal infection	12
037	Tetanus	1
038	Septicemia	300
039	Actinomycotic infections	1
040	Other bacterial diseases	8
041	Bacterial infection in conditions classified elsewhere and of unspecified site	8
046	Slow virus infection of central nervous system	8
047	Meningitis due to enterovirus	2
048	Other enterovirus diseases of central nervous system	1
049	Other non-arthropod-borne viral diseases of central nervous system	8
052	Chickenpox	3
053	Herpes zoster	5
054	Herpes simplex	5
070	Viral hepatitis	26
075	Infectious mononucleosis	1
078	Other diseases due to viruses and chlamydiae	3
079	Viral infection in conditions classified elsewhere and of unspecified site	8
090	Congenital syphilis	2
093	Cardiovascular syphilis	3
094	Neurosyphilis	4
112	Candidiasis	13
114	Coccidioidomycosis	1
117	Other mycoses	8
135	Sarcoidosis	14
136	Other and unspecified infectious and parasitic diseases	11
137	Late effects of tuberculosis	14
138	Late effects of acute poliomyelitis	2
II.	NEOPLASMS (140-239)	
140	Malignant neoplasm of lip	4
141	Malignant neoplasm of tongue	84
142	Malignant neoplasm of major salivary glands	17
143	Malignant neoplasm of gum	3
144	Malignant neoplasm of floor of mouth	18
145	Malignant neoplasm of other and unspecified parts of mouth	51
146	Malignant neoplasm of oropharynx	32
147	Malignant neoplasm of nasopharynx	20
148	Malignant neoplasm of hypopharynx	34
149	Malignant neoplasm of other and ill-defined sites within the lip oral cavity and pharynx	54
150	Malignant neoplasm of oesophagus	277
151	Malignant neoplasm of stomach	596
152	Malignant neoplasm of small intestine, including duodenum	32
153	Malignant neoplasm of colon	1,597
154	Malignant neoplasm of rectum, rectosigmoid junction and anus	359
155	Malignant neoplasm of liver and intrahepatic bile ducts	199
156	Malignant neoplasm of gallbladder and extrahepatic bile ducts	175
157	Malignant neoplasm of pancreas	799
158	Malignant neoplasm of retroperitoneum and peritoneum	18
159	Malignant neoplasm of other and ill-defined sites within the digestive organs and peritoneum	83
160	Malignant neoplasm of nasal cavities, middle ear and accessory sinuses	19
161	Malignant neoplasm of larynx	137
162	Malignant neoplasm of trachea, bronchus and lung	3,744
163	Malignant neoplasm of pleura	6
164	Malignant neoplasm of thymus, heart and mediastinum	11
170	Malignant neoplasm of the bone and articular cartilage	56
171	Malignant neoplasm of connective and other soft tissue	104
172	Malignant melanoma of skin	145
173	Other malignant neoplasm of skin	45
174	Malignant neoplasm of female breast	1,305
175	Malignant neoplasm of male breast	14
179	Malignant neoplasm of uterus, part unspecified	115
180	Malignant neoplasm of cervix uteri	174
181	Malignant neoplasm of placenta	1
182	Malignant neoplasm of body of uterus	114
183	Malignant neoplasm of ovary and other uterine adnexa	386
184	Malignant neoplasm of other and unspecified female genital organs	31
185	Malignant neoplasm of prostate	840
186	Malignant neoplasm of testis	25
187	Malignant neoplasm of penis and other male genital organs	11
188	Malignant neoplasm of bladder	418
189	Malignant neoplasm of kidney and other and unspecified urinary organs	278
190	Malignant neoplasm of eye	10
191	Malignant neoplasm of brain	363
192	Malignant neoplasm of other and unspecified parts of nervous system	15
193	Malignant neoplasm of thyroid gland	34
194	Malignant neoplasm of other endocrine glands and related structures	13
195	Malignant neoplasm of other and ill-defined sites	104
199	Malignant neoplasm without specification of site	969
200	Lymphosarcoma and reticulosarcoma	208
201	Hodgkin's disease	86
202	Other malignant neoplasm of lymphoid and histiocytic tissue	282
203	Multiple myeloma and immunoproliferative neoplasm	274
204	Lymphoid leukemia	178
205	Myeloid leukemia	271
206	Monocytic leukemia	20
207	Other specified leukemia	15
208	Leukemia of unspecified cell type	135
211	Benign neoplasm of other parts of digestive system	8
212	Benign neoplasm of respiratory and intrathoracic organs	1
213	Benign neoplasm of bone and articular cartilage	3
215	Other benign neoplasm of connective and other soft tissue	2
218	Uterine leiomyoma	1
220	Benign neoplasm of ovary	1
225	Benign neoplasm of brain and other parts of nervous system	24
226	Benign neoplasm of thyroid gland	1
227	Benign neoplasm of other endocrine glands and related structures	11
228	Hemangioma and lymphangioma, any site	2
235	Neoplasm of uncertain behaviour of digestive and respiratory systems	5
237	Neoplasm of uncertain behaviour of endocrine glands and nervous system	12
238	Neoplasm of uncertain behaviour of other and unspecified sites and tissues	36
239	Neoplasm of unspecified nature	108
III.	ENDOCRINE, NUTRITIONAL AND METABOLIC DISEASES AND IMMUNITY DISORDERS (240-279)	
242	Thyrotoxicosis with or without goitre	11
244	Acquired hypothyroidism	15
250	Diabetes mellitus	1,449
251	Other disorders of pancreatic internal secretion	1
252	Disorders of parathyroid gland	1
253	Disorders of the pituitary gland and it's hypothalamic control	7
254	Diseases of the thymus gland	1
255	Disorders of the adrenal glands	16
259	Other endocrine disorders	2
260	Kwashiorkor	1
261	Nutritional marasmus	7
263	Other and unspecified protein-calorie malnutrition	71
269	Other nutritional deficiencies	4
270	Disorders of amino-acid transport and metabolism	2
271	Disorders of carbohydrate transport and metabolism	2
272	Disorders of lipoid metabolism	26
273	Disorders of plasma protein metabolism	15
274	Gout	3
275	Disorders of mineral metabolism	8
276	Disorder of fluid electrolyte and acid-base balance	133
277	Other and unspecified disorders of metabolism	46
278	Obesity and other hyperalimentation	45
279	Disorders involving the immune mechanism	3
IV.	DISEASES OF BLOOD AND BLOOD-FORMING ORGANS (280-289)	
280	Iron deficiency anaemias	3
281	Other deficiency anaemias	6
282	Hereditary haemolytic anaemias	19
283	Acquired haemolytic anaemias	11

NUMBER OF DEATHS BY CAUSE
MICHIGAN RESIDENTS, 1979 (continued)

ICD LIST NUMBER	CAUSE OF DEATH	NUMBER
284	Aplastic anaemia	55
285	Other and unspecified anaemias	37
286	Coagulation defects	43
287	Purpura and other haemorrhagic conditions	27
288	Diseases of white blood cells	13
289	Other diseases of blood and blood forming organs	37
	V. MENTAL DISORDERS (290-319)	
290	Senile and presentle organic psychotic conditions	42
291	Alcoholic psychoses	10
292	Drug psychoses	1
293	Transient organic psychotic conditions	1
295	Schizophrenic psychoses	2
298	Other nonorganic psychoses	10
299	Psychoses with origin specific to childhood	1
300	Neurotic disorders	3
303	Alcohol dependence syndrome	104
304	Drug dependence	12
305	Nondependent abuse of drugs	83
307	Special symptoms or syndromes not elsewhere classified	6
308	Acute reaction to stress	1
310	Specific nonpsychotic mental disorders following organic brain damage	112
311	Depressive disorder, not elsewhere classified	2
318	Other specified mental retardation	16
319	Unspecified mental retardation	14
	VI. DISEASES OF THE NERVOUS SYSTEM AND SENSE ORGANS (320-389)	
320	Bacterial meningitis	27
322	Meningitis of unspecified cause	21
323	Encephalitis, myelitis and encephalomyelitis	8
324	Intracranial and intraspinal abscess	12
326	Late effects of intracranial abscess or pyogenic infection	5
330	Cerebral degenerations usually manifest in childhood	3
331	Other cerebral degenerations	93
332	Parkinson's disease	108
333	Other extrapyramidal	18
334	Spinocerebellar disease	1
335	Anterior horn cell disease	113
336	Other diseases of spinal cord	4
340	Multiple sclerosis	57
341	Other demyelinating diseases of central nervous system	11
342	Hemiplegia	17
343	Infantile cerebral palsy	30
344	Other paralytic syndromes	36
345	Epilepsy	71
348	Other conditions of brain	90
349	Other and unspecified disorders of the nervous system	4
352	Disorders of other cranial nerves	1
355	Mononeuritis of lower limb	2
356	Hereditary and idiopathic peripheral neuropathy	6
357	Inflammatory and toxic neuropathy	9
358	Myoneural disorders	14
359	Muscular dystrophies and other myopathies	32
360	Disorders of the globe	1
382	Suppurative and unspecified otitis media	3
383	Mastoiditis and related conditions	1
	VII. DISEASES OF THE CIRCULATORY SYSTEM (390-459)	
390	Rheumatic fever without mention of heart involvement	2
391	Rheumatic fever with heart involvement	8
394	Diseases of mitral valve	129
395	Diseases of aortic valve	19
396	Diseases of mitral and aortic valves	35
397	Diseases of other endocardial structures	16
398	Other rheumatic heart disease	101
401	Essential hypertension	97
402	Hypertensive heart disease	744
403	Hypertensive renal disease	172
404	Hypertensive heart and renal disease	110

NUMBER OF DEATHS BY CAUSE
MICHIGAN RESIDENTS, 1979 (continued)

ICD LIST NUMBER	CAUSE OF DEATH	NUMBER
536	Disorders of function of stomach	5
537	Other disorders of stomach and duodenum	24
540	Acute appendicitis	27
541	Appendicitis, unqualified	2
543	Other diseases of appendix	1
550	Inguinal hernia	10
551	Other hernia of abdominal cavity, with gangrene	2
552	Other hernia abdominal cavity with obstruction, without mention of gangrene	18
553	Other hernia of abdominal cavity without mention of obstruction or gangrene	28
555	Regional enteritis	12
556	Idiopathic proctocolitis	10
557	Vascular insufficiency of intestine	154
558	Other noninfective gastroenteritis and colitis	34
560	Intestinal obstruction without mention of hernia	159
562	Diverticula of intestine	124
564	Functional digestive disorders, not elsewhere classified	6
566	Abscess of anal and rectal regions	6
567	Peritonitis	54
568	Other disorders of peritoneum	6
569	Other disorders of intestine	50
570	Acute and subacute necrosis of liver	13
571	Chronic liver disease and cirrhosis	1,367
572	Liver abscess and sequelae of chronic liver disease	110
573	Other disorders of liver	35
574	Cholelithiasis	40
575	Other disorders of gallbladder	49
576	Other disorders of biliary tract	33
577	Diseases of pancreas	109
578	Gastrointestinal haemorrhage	164
579	Intestinal malabsorption	11
	X. DISEASES OF THE GENITOURINARY SYSTEM (580-629)	
580	Acute glomerulonephritis	6
581	Nephrotic syndrome	9
582	Chronic glomerulonephritis	60
583	Nephritis and nephritis and nephropathy, not specified as acute or chronic	14
584	Acute renal failure	78
585	Chronic renal failure	141
586	Renal failure, unspecified	287
587	Renal sclerosis, unspecified	2
588	Disorders resulting from impaired renal function	4
590	Infections of kidney	76
591	Hydronephrosis	5
592	Calculus of kidney and ureter	13
593	Other disorders of kidney and ureter	34
595	Cystitis	7
596	Other disorders of bladder	6
597	Urethritis, not sexually transmitted, and urethral syndrome	3
598	Urethral stricture	2
599	Other disorders of urethra and urinary tract	125
600	Hypeplasia of prostate	19
602	Other disorders of prostate	9
611	Other disorders of breast	2
614	Inflammatory disease of ovary, fallopian tube, pelvic cellular tissue and peritoneum	7
618	Genital prolapse	1
619	Fistulae involving female genital tract	1
621	Disorders of uterus, not elsewhere classified	1
623	Noninflammatory disorders of vagina	2
626	Disorders of menstruation and other abnormal bleeding from female genital tract	1
	XI. COMPLICATIONS OF PREGNANCY, CHILDBIRTH, AND THE PUERPERIUM (630-676)	
633	Ectopic pregnancy	2
636	Illegally induced abortion	1
642	Hypertension complicating pregnancy	1
648	Other current conditions in the mother classifiable elsewhere but complicating pregnancy, childbirth and the puerperium	1
666	Postpartum haemorrhage	1
669	Other complications of labour and delivery, not elsewhere classified	1
670	Major puerperal infections	1
671	Venous complications in pregnancy and the puerperium	1
673	Obstetrical pulmonary embolism	2
	XII. DISEASES OF THE SKIN AND SUBCUTANEOUS TISSUE (680-709)	
682	Other cellulitis and abscess	18
683	Acute lymphadenitis	1
686	Other local infections of skin and subcutaneous tissue	4
692	Contact dermatitis and related conditions	1
694	Bullous dermatoses	3
695	Erythematous conditions	4
705	Disorders of sweat glands	1
707	Chronic ulcer of skin	60
	XIII. DISEASES OF THE MUSCULOSKELETAL SYSTEM AND CONNECTIVE TISSUE (710-739)	
710	Diffuse diseases of connective tissue	68
711	Arthropathy associated with infections	2
714	Rheumatoid arthritis and other inflammatory polyarthropathies	44
715	Osteoarthosis and allied disorders	16
716	Other and unspecified artropathies	5
718	Other dearrangement of joint	1
719	Other and unspecified disorder of joint	3
720	Ankylosing spondylitis and other inflammatory spondylopathies	2
721	Spondylosis and allied disorders	6
722	Intervertebral disc disorders	1
724	Other and unspecified disorder of back	1
726	Peripheral enthesopathies and allied syndromes	1
728	Disorders of muscle, ligament and fascia	5
729	Other disorders of soft tissues	1
730	Osteomyelitis, periostitis and other infections involving bone	3
731	Osteitis deformans and osteopathies associated with other disorders classified elsewhere	1
733	Other disorders of bone and cartilage	5
737	Curvature of spine	4
738	Other acquired deformity	2
	XIV. CONGENITAL ANOMALIES (740-759)	
740	Anencephalus and similar anomalies	24
741	Spina bifida	12
742	Other congenital anomalies of nervous system	53
745	Bulbus cordis anomalies and anomalies of cardiac septal closure	79
746	Other congenital anomalies of heart	126
747	Other congenital anomalies of circulatory system	49
748	Congenital anomalies of respiratory system	26
750	Other congenital anomalies of upper alimentary tract	2
751	Other congenital anomalies of digestive system	16
752	Congenital anomalies of genital organs	1
753	Congenital anomalies of urinary system	34
754	Certain congenital musculoskeletal deformaties	1
755	Other congenital anomalies of limb	1
756	Other congenital musculoskeletal anomalies	30
757	Congenital anomalies of the integument	4
758	Chromosomal anomalies	38
759	Other and unspecified congenital anomalies	43
	XV. CERTAIN CONDITIONS ORIGINATING IN THE PERINATAL PERIOD (760-779)	
760	Fetus or newborn affected by maternal conditions which may be unrelated to present pregnancy	1
761	Fetus or newborn affected by maternal complications of pregnancy	75
762	Fetus or newborn affected by complications of placenta, cord and membranes	47
763	Fetus or newborn affected by other complications of labour and delivery	9
764	Slow fetal growth and fetal malnutrition	5
765	Disorders relating to short gestation and unspecified low birthweight	134
767	Birth trauma	45
768	Intrauterine hypoxia and birth asphyxia	70
769	Respiratory distress syndrome	260
770	Other respiratory conditions of fetus and newborn	171
771	Infections specific to the perinatal period	33
772	Fetal and neonatal haemorrhage	22
773	Haemolytic disease of fetus or newborn isoimmunization	2
774	Other perinatal jaundice	1
775	Endocrine and metabolic disturbances specific to the fetus and newborn	5
776	Haematological disorders of fetus and newborn	6
777	Perinatal disorders of digestive system	14

TABLE 4.16

NUMBER OF DEATHS BY CAUSE
MICHIGAN RESIDENTS, 1979 (continued)

ICD LIST NUMBER	CAUSE OF DEATH	NUMBER
778	Conditions involving the integument and temperature regulation of fetus and newborn	8
779	Other and ill-defined conditions originating in the perinatal period	116
XVI.	SYMPTOMS, SIGNS AND ILL-DEFINED CONDITIONS (780-799)	
780	General symptoms	8
782	Symptoms involving skin and other integumentary tissue	1
785	Symptoms involving cardiovascular system	19
786	Symptoms involving respiratory system and other chest symptoms	5
788	Symptoms involving urinary system	1
789	Other symptoms involving abdomen and pelvis	1
790	Nonspecific findings on examination of blood	1
797	Senility without mention of psychosis	20
798	Sudden death, cause unknown	254
799	Other ill-defined and unknown causes of morbidity and mortality	166
XVII.	EXTERNAL CAUSES OF INJURY AND POISONING (E800-E999)	
E800	Railway accident involving collision with rolling stock	1
E804	Fall in, on, or from railway train	1
E805	Hit by rolling stock	7
E810	Motor vehicle traffic accident involving collision with train	36
E812	Other motor vehicle traffic accident involving collision with another motor vehicle	816
E813	Motor vehicle traffic accident involving collision with other vehicle	50
E814	Motor vehicle traffic accident collision with pedestrian	350
E815	Other motor vehicle traffic accident involving collision on the highway	192
E816	Motor vehicle traffic accident due to loss of control, without collision on the highway	306
E817	Noncollision motor vehicle traffic accident while boarding or alighting	1
E818	Other noncollision motor vehicle traffic accident	27
E819	Motor vehicle traffic accident of unspecified nature	136
E820	Nontraffic accident involving motor driven snow vehicle	5
E821	Nontraffic accident involving other off-road motor vehicle	1
E822	Other motor vehicle nontraffic accident involving collision with moving object	30
E823	Other motor vehicle nontraffic accident involving collision with stationary object	5
E825	Other motor vehicle nontraffic accident of other and unspecified nature	16
E826	Pedal cycle accident	5
E828	Accident involving animal being ridden	1
E830	Accident to watercraft causing submersion	18
E831	Accident to watercraft causing other injury	1
E832	Other accidental submersion or drowning in water transport accident	18
E835	Other and unspecified fall in water transport	1
E838	Other and unspecified water transport accident	7
E840	Accident to powered aircraft at take off or landing	11
E841	Accident to powered aircraft, other and unspecified	37
E844	Other specified air transport accidents	6
E846	Accidents involving powered vehicles used solely within the building and premises of an industrial or commercial establishment	2
E850	Accidental poisoning by analgesics, antipyretics, antirheumatics	16
E851	Accidental poisoning by barbiturates	1
E852	Accidental poisoning by other sedatives and hypnotics	1
E853	Accidental poisoning by tranquillizers	3
E854	Accidental poisoning by other psychotropic agents	2
E855	Accidental poisoning by other drugs acting on central and autonomic nervous systems	5
E858	Accidental poisoning by other drugs	32
E860	Accidental poisoning by alcohol, not elsewhere classified	5
E861	Accidental poisoning by cleansing and polishing agents, disinfectants, paints, and varnishes	1
E862	Accidental poisoning by petroleum products, other solvents and their vapours not elsewhere classified	2
E866	Accidental poisoning by other and unspecified solid and liquid substances	1
E868	Accidental poisoning by other utility gas distributed by pipeline	1
E869	Accidental poisoning by other gases and vapours	6
E870	Accidental cut puncture, perforation or haemorrhage during medical care	3
E871	Foreign object left in body during procedure	1
E878	Surgical operation and other surgical procedures as the cause of abnormal reaction of patient, or of later complication, without mention of misadventure at the time of operation	51
E879	Other procedures, without mention of misadventure at the time of procedure, as the cause of abnormal reaction of patient, or of later complication	9
E880	Fall on or from stairs or steps	73
E881	Fall on or from ladders or scaffolding	11
E882	Fall from or out of building or other structure	22
E883	Fall into hole or other opening in surface	5
E884	Other fall from one level to another	42
E885	Fall on same level from slipping, tripping, or stumbling	11
E887	Fracture, cause specified	164
E888	Other and unspecified fall	241
E890	Conflagration in private dwelling	237
E891	Conflagration in other and unspecified building or structure	9
E893	Accident caused by ignition of clothing	3
E894	Ignition of highly inflammable material	3
E895	Accident caused by controlled fire in private dwelling	1
E897	Accident caused by controlled fire not in building or structure	1
E898	Accident caused by other specified fire and flames	7
E899	Accident caused by unspecified fire	5
E900	Excessive heat	2
E901	Excessive cold	25
E904	Hunger, thirst, exposure, neglect	21
E907	Lightening	2
E908	Cataclysmic storms, and floods resulting from storms	
E910	Accidental drowning and submersion	185
E911	Inhalation and ingestion of food causing obstruction of respiratory tract or suffocation	92
E912	Inhalation and ingestion of other object causing obstruction of respiratory tract or suffocation	52
E913	Accidental mechanical suffocation	44
E916	Struck accidentally by falling object	46
E917	Striking against or struck accidentally by objects or persons	8
E918	Caught accidentally in or between objects	5
E919	Accidents caused by machinery	38
E920	Accidents caused by cutting and piercing instruments or objects	3
E921	Accidents caused by explosion of pressure vessel	1
E922	Accident caused by firearm missile	58
E923	Accident caused by explosive material	10
E924	Accident caused by hot substance or object caustic or corrosive material and steam	8
E925	Accident caused by electric current	28
E927	Overexertion and strenuous movements	7
E928	Other and unspecified environmental and accidental causes	57
E929	Late effects of accidental injury	30
E947	Other and unspecified drugs and medicaments	7
E950	Suicide and self inflicted poisoning by solid or liquid substances	119
E951	Suicide and self inflicted poisoning by gases in domestic use	3
E952	Suicide and self inflicted poisoning by other gases and vapours	156
E953	Suicide and self inflicted injury by hanging, strangulation, and suffocation	170
E954	Suicide and self inflicted injury by submersion (drowning)	26
E955	Suicide and self inlicted injury by firearms and explosives	602
E956	Suicide and self inlicted injury by cutting and piercing instruments	20
E957	Suicide and self inflicted injuries by jumping from high place	20
E958	Suicide and self inlicted injury by other and unspecified means	29
E960	Fight, brawl, rape	2
E962	Assault by poisoning	1
E963	Assault by hanging and strangulation	38
E964	Assault by submersion (drowning)	3
E965	Assault by firearms and explosives	538
E966	Assault by cutting and piercing instrument	154

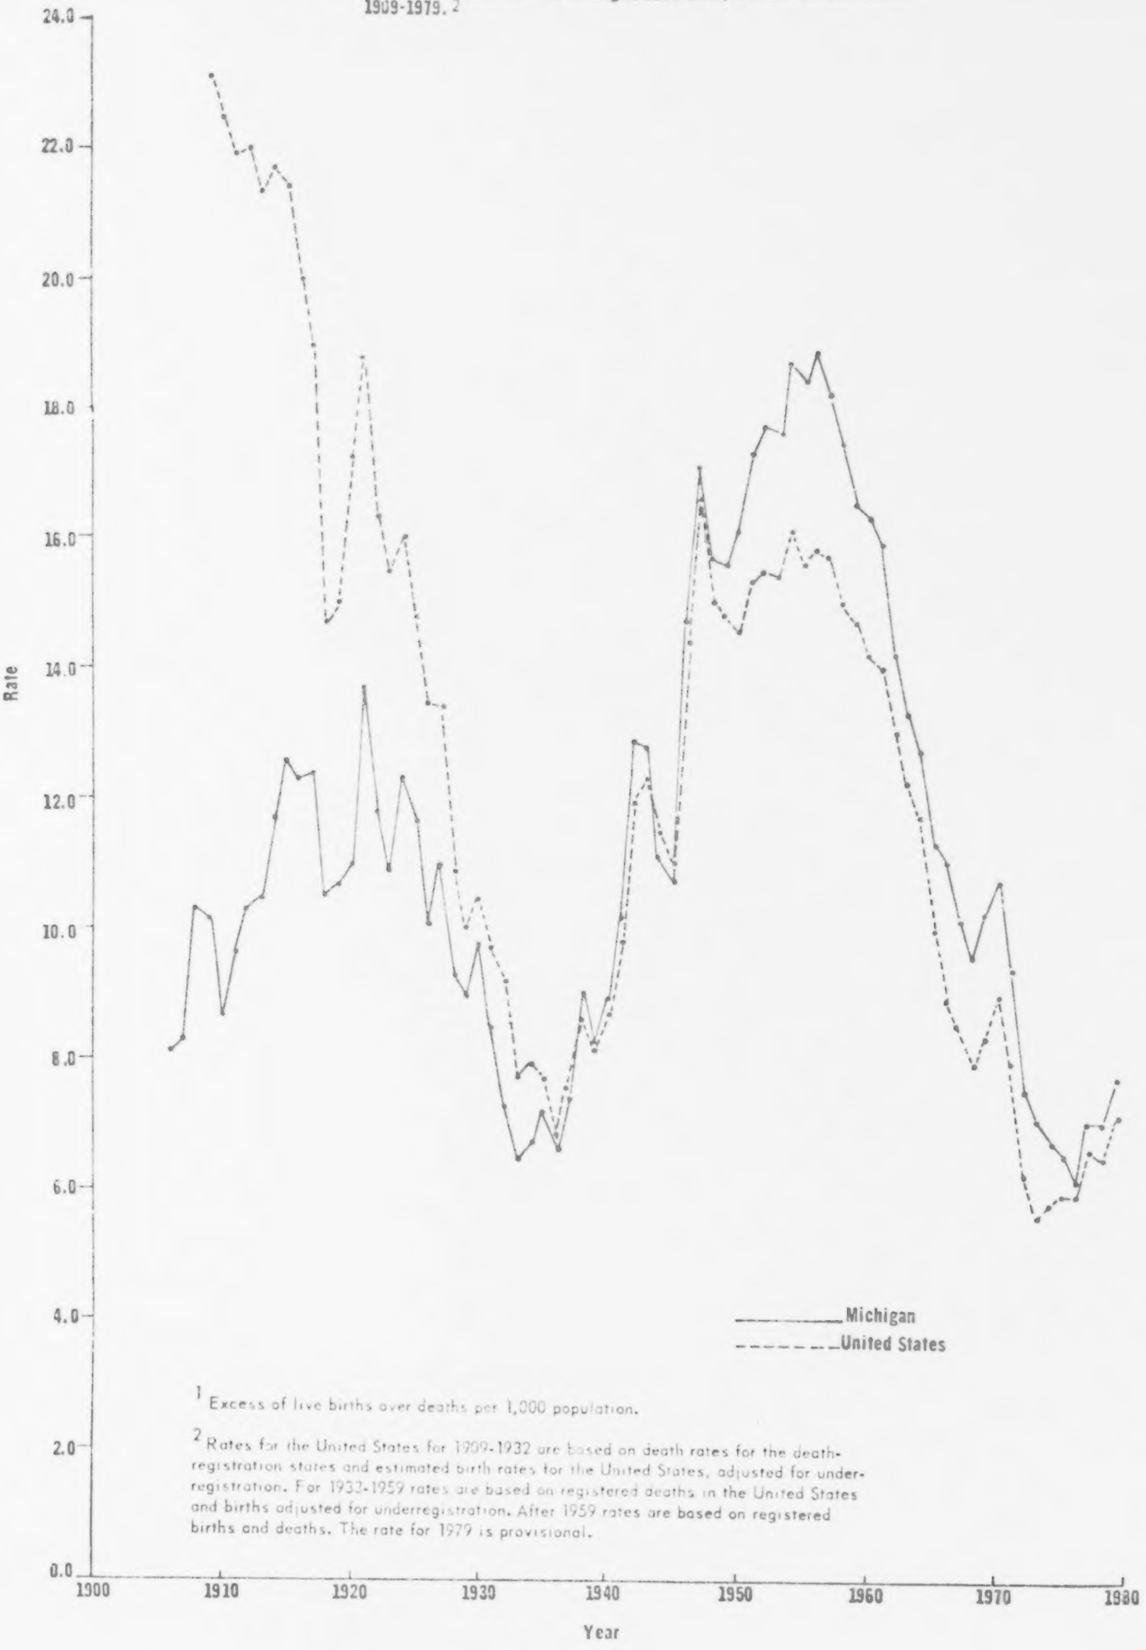
FIGURE 4.7 - Rate of Natural Increase,[1] Michigan 1906-1979, and the United States, 1909-1979.[2]



[1] Excess of live births over deaths per 1,000 population.

[2] Rates for the United States for 1909-1932 are based on death rates for the death-registration states and estimated birth rates for the United States, adjusted for under-registration. For 1933-1959 rates are based on registered deaths in the United States and births adjusted for underregistration. After 1959 rates are based on registered births and deaths. The rate for 1979 is provisional.

INSTRUCTIONS

Michigan Public Act 368 of 1978 requires the reporting of the death of a fetus which has completed 20 weeks of gestation or weighs at least 400 grams to the state registrar within 5 days after delivery. Responsibility for filing fetal death reports lies with the following: 1) the institution where the fetus is delivered; 2) the attending physician if delivered outside an institution, 3) the medical examiner, when investigation by the medical examiner is required.

As these reports are necessary in the development of important statistical health measures for the state, including fetal and perinatal mortality, and the analysis of various variables associated to fetal death outcomes, it is important that each report be as accurate and complete as is possible.

DO NOT REPORT THE NAME OF THE BIOLOGICAL PARENTS, OR OTHER INFORMATION WHICH WOULD MAKE IT POSSIBLE TO IDENTIFY EITHER PARENT.

Michigan Public Act 343 of 1925, as amended, requires that the attending physician, or in the absence of an attending physician a medical examiner shall fill out and sign the medical certificate of death within 48 hours after death.

The funeral director is responsible for completing all other portions of the certificate and obtaining a burial or removal permit prior to disposing of the body or removing from the registration district where the death occurred.

ERRATA

Michigan Health Statistics, 1979
(Annual Statistical Report)

Please make the following corrections in your copy of Michigan Health Statistics, 1979:

Table 4.7 page 326
1972 Typhoid Fever should be 1 and rate 0.0 instead of dash.
1978 Whooping Cough should be 1 and rate 0.0 instead of dash.
1979 Whooping Cough should be dash instead of 1 and 0.0.
1979 T.B. (All Forms) should be 62 and rate 0.7 instead of 76 and rate 0.8.

Table 2.29 page 194
Reference in subscript "2" should be to Table 2.7 instead of Table 2.6.

Narration "Racial Composition" page 33 line 10
should be "increased by 10.0 percent and 7.4 percent respectively.",
instead of "increased by 8.2 percent and 7.4 percent respectively.".
